February 1991, Revised April 1995  
Printed in USA

***Giga-tronics***

# WARRANTY

Notwithstanding any provision of any agreement, the following warranty is exclusive:

Giga-tronics Inc. warrants each instrument it manufactures to be free from defects in material and workmanship under normal use and service for the period of one year from the date of shipment. This warranty extends only to the original purchaser. This warranty shall not apply to fuses, disposable batteries (rechargeable batteries are warranted for 90 days), or any product or parts which have been subject to misuse, neglect, accident, or abnormal conditions of operation.

In the event of failure of a product covered by this warranty, Giga-tronics Inc. will repair and calibrate an instrument returned to an authorized service facility within one year of the original shipment, provided that examination discloses to the satisfaction of Giga-tronics that the product was defective. Giga-tronics may, at its option, replace the product in lieu of repairing it. With regard to any instrument returned within one year of the original shipment, said repairs or replacement will be made without charge. If the failure has been caused by misuse, neglect, accident, or abnormal conditions of operation, repairs will be billed at a nominal cost. In such cases, an estimate will be submitted before work is started, if requested.

THE FOREGOING WARRANTY IS IN LIEU OF ALL OTHER WARRANTIES, EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS, OR ADEQUACY FOR ANY PARTICULAR PURPOSE OR USE. GIGA-TRONICS INC. SHALL NOT BE LIABLE FOR ANY SPECIAL, INCIDENTAL, OR CONSEQUENTIAL DAMAGES, WHETHER IN CONTRACT, TORT, OR OTHERWISE.

## IF ANY FAILURE OCCURS, THE FOLLOWING STEPS SHOULD BE TAKEN:

1. Notify Giga-tronics Inc., or the nearest authorized service facility (see the list of service centers at the end of Chapter 8), giving full details of the difficulty, and include the model number, type number, and serial number. On receipt of this information, service data or shipping instructions will be forwarded to you.
2. On receipt of the shipping instructions, forward the instrument, transportation prepaid. Repairs will be made at the service facility and the instrument returned, transportation prepaid.

## SHIPPING TO THE MANUFACTURER FOR REPAIR OR ADJUSTMENT

All shipments of Giga-tronics instruments should be made prepaid (air freight recommended). Ship the instrument in the original packing carton; or, if that is not available, use any suitable container that is rigid and of adequate size. If a substitute container is used, the instrument should be wrapped in paper and surrounded with at least four inches of excelsior or similar shock-absorbing material.

## CLAIM FOR DAMAGE IN SHIPMENT TO THE ORIGINAL PURCHASER

The instrument should be thoroughly inspected immediately upon original delivery to the purchaser. All material in the container should be checked against the enclosed packing list. The manufacturer will not be responsible for shortages against the packing sheet unless notified immediately. (To obtain a quotation to repair shipment damage, contact Giga-tronics Inc., or any of its authorized service facilities.) Final claim and negotiations with the carrier must be completed by the customer.

Giga-tronics Inc. will be happy to answer all questions about applications, in order to enhance your use of the instrument. Please address your requests or correspondence to:

GIGA-TRONICS INC., 4650 NORRIS CANYON ROAD, SAN RAMON, CALIFORNIA, 94583, ATTN: SERVICE.

# SAFETY SUMMARY

## SAFETY TERMS IN THIS MANUAL

This instrument has been designed and tested in accordance with IEC Publication 348, Safety Requirements for Electronic Measuring Apparatus. This Service Manual contains information, warnings, and cautions that must be followed to ensure safe maintenance and to keep the Signal Generator in a safe condition.

**WARNING** statements identify conditions or practices that could result in personal injury or loss of life.

**CAUTION** statements identify conditions or practices that could result in damage to equipment.

## SYMBOLS MARKED ON EQUIPMENT

DANGER — High voltage.

Ground (earth) terminal.

Attention — refer to the manual. This symbol indicates that information about the use of a feature is contained in the manual.

## POWER SOURCE

The Signal Generator is intended to operate from a power source that will not apply more than 264V ac rms between the supply conductors or between either supply conductor and ground. A protective ground connection by way of the grounding conductor in the power cord is essential for safe operation.

## USE THE PROPER FUSE

To avoid fire hazard, use only a fuse identical in type, voltage rating, and current rating to that specified on the rear panel fuse rating label.

## GROUNDING THE INSTRUMENT

The Signal Generator is a Safety Class I (grounded enclosure) instrument as defined in IEC 348. The enclosure is grounded through the grounding conductor of the power cord. To avoid electrical shock, plug the power cord into a properly wired earth grounded receptacle before connecting anything to any of the Signal Generator connectors. A protective ground connection by way of the grounding conductor in the power cord is essential for safe operation.

**USE THE PROPER POWER CORD**

Use only the power cord and connector appropriate for the voltage and plug configuration in your country.

Use only a power cord that is in good condition.

Refer cord and connector changes to qualified service personnel.

**DO NOT OPERATE IN EXPLOSIVE ATMOSPHERES**

To avoid explosion, do not operate the Signal Generator in an atmosphere of explosive gas.

**DO NOT ATTEMPT TO OPERATE IF ELECTRIC SHOCK PROTECTION MAY BE IMPAIRED**

If the Signal Generator appears damaged or operates abnormally, protection from electric shock may be impaired. Do not attempt to operate it. When in doubt, have the instrument serviced.

**DO NOT REMOVE COVER UNLESS QUALIFIED TO DO SO**

To avoid electric shock, do not remove the Signal Generator cover unless you are qualified to do so. Service procedures are for qualified service personnel only.

**DO NOT SERVICE ALONE**

Do not perform internal service or adjustment of this product unless a person capable of rendering first aid and resuscitation is present.

**USE CARE WHEN SERVICING WITH POWER ON**

Dangerous voltages exist at several points inside this product. To avoid personal injury, do not touch exposed connections and components while the power is on.

**UNPLUG POWER CORD TO REMOVE INSTRUMENT POWER**

This product remains energized when the POWER switch is in the STBY position. Disconnect incoming ac power by unplugging the power cord before removing protective panels, soldering, or replacing components.

**6082A Synthesized RF Signal Generator**

# Section 1

## Introduction and Specifications

### INTRODUCTION

1-1.

The Model 6082A Synthesized RF Signal Generator is a fully programmable, precision, synthesized signal source. The 6082A is designed for applications that require good modulation, frequency accuracy, and output level performance with excellent spectral purity. The 6082A is well suited for testing a wide variety of RF components, subassemblies, and systems, including filters, amplifiers, mixers, and receivers, particularly off-channel radio testing.

Refer to the 6080A/82A Operator Manual for operating instructions, use of the front and rear panel features, remote programming, and all other information for the operator.

This service manual is a maintenance guide for the Signal Generator. The following topics are included:

- Theory of operation
- Closed-case calibration
- Performance testing
- Access procedures
- Troubleshooting and alignment
- Parts lists
- Schematic diagrams

### OPTIONS

1-2.

Three options are available for the 6082A:

1. 6080A-830 Rear Output and Modulation Input
2. 6080A-130 High Stability Reference (see Specifications)
3. 6080A-132 Medium Stability Reference (see Specifications)

Theory of operation and schematics for these options are contained in the Options section in the 6082A Service Manual.

Refer to the Giga-tronics catalog for price and ordering information. All three options are factory installable only.

## INTRODUCTION AND SPECIFICATIONS

### OBTAINING FACTORY SERVICE

1-3.

Factory authorized service for the Signal Generator is available at selected Fluke Technical Service Centers. For service, return the Signal Generator to the nearest Fluke Technical Service Center. The local service center will handle transportation to and from the selected service center as required. A complete list of Fluke Sales and Technical Service Centers is provided following the parts lists in Section 8.

To reship the Signal Generator, use its original shipping carton. If the original carton is not available, use a container that provides adequate protection during shipment. Protect the Signal Generator with at least three inches of shock-absorbing material on all sides of the container. Do not use loose fill to pad the shipping container. Loose fill allows the signal generator to settle to one corner of the shipping container, which could result in damage during shipment.

### SPECIFICATIONS

1-4.

Table 1-1 lists specifications for the 6082A. Specifications are valid after a warm-up period of 20 minutes. Specifications remain valid after 2 years only if the 6082A is calibrated as described in this manual, and every 2 years or more frequently thereafter. In the specification table, dBc refers to decibels relative to the amplitude of the carrier.

Table 1-1. Specifications for Model 6082A

FREQUENCY		
Range: 100 kHz to 2112 MHz. (See Internal Modulation Oscillator for coverage from 0.1 Hz to 200 kHz.)		
Frequency Bands: The carrier frequency band endpoints are shown below.		
BAND DESIGNATION	APPROXIMATE CARRIER FREQUENCY BAND (MHz)	SPECIFIC CARRIER FREQUENCY BAND (MHz)
A	0.1 to 15	0.1 to 14.999,999
B	15 to 32	15 to 31.999,999
C	32 to 64	32 to 63.999,999
D	64 to 128	64 to 127.999,999
E	128 to 256	128 to 255.999,999
F	256 to 512	256 to 511.999,999
G	512 to 1056	512 to 1055.999,999
H	1056 to 2112	1056 to 2112

**Resolution:** 1 Hz  
**Display Resolution:** 10 digits  
**Stability:** Same as Internal Reference Oscillator

**10 MHz INTERNAL REFERENCE OSCILLATOR**  
**Type:** Temperature Compensated Crystal Oscillator (TCXO)  
**Temperature Stability:** Less than  $\pm 1$  ppm p-p over the range 0 to +50°C  
**Typical Aging Rate:** Less than  $\pm 1$  ppm/yr  
**Reference Output:** 10 MHz, >0 dBm for 50Ω load, available at the rear panel REF OUT connector.

**PROVISION FOR EXTERNAL REFERENCE**  
 The rear panel REF IN connector accepts an external source of 10 MHz  $\pm 10$  ppm sine wave, 0.2 to 2.0V rms for a 50Ω load. One alternate external reference frequency setting of 1, 2, or 5 MHz is available at a time, through Special Function 761 or a remote command. The default alternate reference frequency is 5 MHz. See the Service Manual for setting internal DIP switches for use with a 1 or 2 MHz external reference.

**AMPLITUDE**  
**Range:** +16 to -140 dBm for RF output frequency <1056 MHz.  
 +13 to -140 dBm for RF output frequency >1056 MHz.  
**Resolution:** 0.1 dB (0.1% or 1 nV in volts). Annunciators for dB, dBm, V, mV,  $\mu$ V, dBf, dB $\mu$ V, dBmV, and EMF  
**Display Resolution:** 3 1/2 digits

**Accuracy (+23 to  $\pm 5^\circ$ C):**

FREQUENCY (MHz)	AMPLITUDE IN dBm			
	+16	+13	-127	-140
0.1 to 0.4	← ±2 dB →		← ±3 dB →	
0.4 to 1056	← ±1 dB →		← ±3 dB →	
1056 to 2112	← ±1 dB →		← ±3 dB →	

# INTRODUCTION AND SPECIFICATIONS

Table 1-1. Specifications for Model 6082A (cont)

Accuracy (0 to 50°C):		
FREQUENCY (MHz)	AMPLITUDE IN dBm	
	+16	+13
0.1 to 0.4	← ±2 dB → ← ±3 dB →	
0.4 to 1056	← ±1.5 dB → ← ±3 dB →	
1056 to 2112	← ±1.5 dB → ← ±3 dB →	
Source SWR: <1.5:1 below +1 dBm <2.0:1 above +1 dBm Flatness (0 to 50°C): ±1.0 dB at +10 dBm Intermodulation Distortion (Amplitude of +4 dBm, CW only):		
FREQUENCY (MHz)	SPACING	
	1 kHz	25 kHz
0.1 to 128 MHz	-60 dBc	-75 dBc
128 to 512 MHz	-65 dBc	-75 dBc
512 to 2121 MHz	-65 dBc	-70 dBc
<b>SPECTRAL PURITY (CW ONLY)</b>		
<b>Spurious Signals:</b> <-100 dBc for offsets greater than 10 kHz and RF output frequency <1056 MHz. <94 dBc for offsets greater than 10 kHz and RF output frequency >1056 MHz. Fixed-frequency spurious signals for RF output frequency <1056 MHz are <-100 dBc or <-140 dBm, whichever is greater. Fixed-frequency spurious signals for RF output frequency >1056 MHz are <-94 dBc or <-140 dBm, whichever is greater.		
<b>Harmonics:</b> <-30 dBc for amplitudes less than +13 dBm at 1 to 2112 MHz.		
<b>Subharmonics:</b> <-45 dBc for RF output frequencies from 1056 to 2112 MHz.		
<b>Power Line Spurious Signals (offsets less than 10 kHz):</b> <-56 dBc for RF output frequencies <1056 MHz. <-50 dBc for RF output frequencies >1056 MHz.		
<b>Residual FM: (NOTE 1)</b>		
FREQUENCY BAND (MHz)	RESIDUAL FM	
	0.3 to 3 kHz	50 Hz to 15 kHz
0.1 to 15	0.2	0.4
15 to 32	0.2	0.4
32 to 64	0.2	0.4
64 to 128	0.2	0.4
128 to 256	0.4	0.5
256 to 512	0.7	1.0
512 to 1056	1.5	2.0
1056 to 2112	3.0	4.0
<b>NOTE 1:</b> Allowable operating modes CW, AM, FM (peak dev. <1.5% of max in operating band), $\emptyset$ M (same comment as FM), Pulse.		

Table 1-1. Specifications for Model 6082A (cont)

SSB Phase Noise: (NOTE 1)			
CARRIER FREQUENCY BAND (MHz)	OFFSET FREQUENCY		
	1 kHz (dBc/Hz)	20 kHz (dBc/Hz)	100 kHz (dBc/Hz)
0.1 to 15	-112	-137	-137
15 to 32	-124	-144	-144
32 to 64	-118	-143	-144
64 to 128	-112	-143	-144
128 to 256	-106	-140	-143
256 to 512	-100	-136	-142
512 to 1056	-94	-131	-138
1056 to 2112	-88	-125	-132

**Residual AM (50 Hz to 15 kHz Band):** < .01% (-80 dBc)

**AMPLITUDE MODULATION**

**Depth Range:** 0% to 99.9% for RF output level <+7 dBm

**AM Resolution:** 0.1%

**AM Display:** 3 digits

**AM Accuracy:**  $\pm(2\% + 4\% \text{ of setting})$  for rate = 1 kHz and depth <90%

**AM Distortion (Rate = 1 kHz) (NOTE 2):** <1.5% THD to 30% AM  
<3% THD to 70% AM  
<5% THD to 90% AM

**AM 3-dB Bandwidth (NOTE 2):** AC-coupled AM, 20 Hz to 50 kHz  
DC-coupled AM, dc to 50 kHz

**Incidental  $\emptyset$ M:** <0.20 radian at 1 kHz rate and 30% AM

**FREQUENCY MODULATION (NOTE 3)**

**FM Display Ranges:** 0 to 999 Hz Dev, 1 Hz Resolution  
and Resolution 1 to 9.99 kHz Dev, 10 Hz Resolution  
10 to 99.9 kHz Dev, 100 Hz Resolution  
100 to 999 kHz Dev, 1 kHz Resolution  
1 to 8.00 MHz Dev, 10 kHz Resolution

**NOTE 2:** AM specifications apply where (RF output frequency - mod frequency) is greater than 150 kHz.

**NOTE 3:** FM specifications apply where: (RF output frequency - deviation) >150 kHz and RF output frequency - mod rate) >150 kHz.

INTRODUCTION AND SPECIFICATIONS

Table 1-1. Specifications for Model 6082A (cont)

Maximum Deviation:				
FREQUENCY BAND (MHz)	MAXIMUM DEVIATION			
	DC-COUPLED FM	AC-COUPLED FM (the smaller of)		
		ABSOLUTE MAXIMUM	RATE LIMITED MAXIMUM	
			DEV ≥ 1/64 MAX	DEV < 1/64 MAX
0.01 to 15	500 kHz	500 kHz	fmod x 5000	fmod x 78
15 to 32	125 kHz	125 kHz	fmod x 1250	fmod x 19
32 to 64	250 kHz	250 kHz	fmod x 2500	fmod x 39
64 to 128	500 kHz	500 kHz	fmod x 5000	fmod x 78
128 to 256	1 MHz	1 MHz	fmod x 10000	fmod x 156
256 to 512	2 MHz	2 MHz	fmod x 20000	fmod x 312
512 to 1056	4 MHz	4 MHz	fmod x 40000	fmod x 625
1056 to 2112	8 MHz	8 MHz	fmod x 80000	fmod x 1250

**FM Distortion:**  
**Standard Mode:** <2% for 0.5 to 1.0 times maximum deviation; <1% for <0.5 times maximum deviation. Applies for rates of 50 Hz to 50 kHz.  
**Low-Distortion Mode (Special Function 731):** <0.3% for @ 3.5 kHz peak deviation and rates 0.3 to 3 kHz.  
**FM Accuracy:** ±(5% of setting + 10 Hz) for rates of 50 Hz to 50 kHz  
**FM 3-dB Bandwidth:**

DEVIATION	COUPLING	
	INTERNAL AC	EXTERNAL AC (DC)
0% to 25% Maximum	20 Hz to 175 kHz	20 Hz (dc) to 175 kHz
25% to 100% Maximum	20 Hz to 100 kHz	20 Hz (dc) to 100 kHz

**Incidental AM:** <1% depth for peak deviation <100 kHz at 1 kHz rate and carrier frequency >0.5 MHz  
**DC-Coupled FM Center Frequency Error, at 1 GHz, after dcFM internal cal, and without any FM range changes:** <(0.1% of dev + 500 Hz)  
**Low-Rate External AC-Coupled FM (Special Function 711):**

FREQUENCY BAND (MHz)	MAX DEV, IN kHz (AT 10 Hz RATE)	
	SINE WAVE	SQUARE WAVE
0.01 to 15	80	40
15 to 32	20	10
32 to 64	40	20
64 to 128	80	40
128 to 256	160	80
256 to 512	320	160
512 to 1056	640	320
1056 to 2112	1280	640

Table 1-1. Specifications for Model 6082A (cont)

<p><b>Droop:</b> &lt;30% on a 5 Hz square wave  <b>3-dB Bandwidth:</b> 0.5 Hz to 100 kHz (typical)  <b>Maximum DC Input:</b> ±10 mV  <b>Incidental AM:</b> &lt;1% AM at 1 kHz rate and &lt;10 kHz deviation</p>	
<p><b>PHASE MODULATION (NOTE 4)</b>  <b>Display Ranges:</b> 0 to .999 radians                                    1 to 9.99 radians                                    10 to 99.9 radians                                    100 to 800 radians  <b>Display Resolution:</b> 3 digits  <b>Maximum Deviation:</b></p>

<p><b>NOTE 4:</b> Phase modulation specifications are valid where (RF frequency - mod frequency) &gt;150 kHz.  <b>NOTE 5:</b> Valid for rates from 50 Hz to 50 kHz in high-bandwidth mode. Does not include effects of residual phase noise.</p>	

## INTRODUCTION AND SPECIFICATIONS

Table 1-1. Specifications for Model 6082A (cont)

### High-Rate Phase Modulation 3-dB Bandwidth (Special Function 721):

AC-coupled phase modulation, 20 Hz to 100 kHz

DC-coupled phase modulation, dc to 100 kHz

Incidental AM (valid for  $f > 500$  kHz):  $<1\%$  AM at 1-kHz rate for peak deviation  $<10$  radians.

### PULSE MODULATION (For RF Output Frequencies $>10$ MHz)

On/Off Ratio: 80 dB minimum

Rise and Fall Times:  $<15$  ns, 10% to 90%

Level Error: For pulse widths  $>50$  ns, the power in the pulse is within  $\pm 0.7$  dB of the measured CW level.

Duty Cycle (External Modulation): 0 to 100%

Repetition Rate (External Modulation): DC to 10 MHz

Internal Modulation: Internal rates and widths

External Modulation: The pulse input is TTL compatible, terminated in  $50\Omega$  with internal active pull-up. It can be modeled as 1.2V in series with  $50\Omega$  at the pulse mod input connector. The instrument senses input terminal voltage and turns the RF OUTPUT off when the terminal voltage drops below  $1\pm 0.1V$ . The maximum allowable input is  $\pm 10V$ .

### PULSE MODULATION (For RF Output Frequencies $<10$ MHz)

Rise and Fall Times:  $<2$  times the period of the RF output frequency

Level Error: For pulse widths  $>10$  times the period of the RF output frequency, the power in the pulse is within  $\pm 0.7$  dB of the measured CW level.

Other pulse specifications are the same as for the  $>10$  MHz frequency range.

### NONVOLATILE INSTRUMENT STATE MEMORY

50 instrument states are retained for typically 2 years, even with ac line power disconnected.

### REVERSE-POWER PROTECTION

Protection Level: Up to 25 watts from a  $50\Omega$  source; up to 25V dc. RF OUTPUT is ac coupled. Protection is provided when the signal generator is turned off.

Trip/Reset: A flashing RF OFF annunciator indicates a tripped condition. Pressing RF ON/OFF button resets the signal generator.

### IEEE-488 REMOTE CONTROL

Extent of Remote Control: All controls except the POWER, REF/INT EXT, and CAL/COMP switches are remotely programmable via the IEEE-488 Interface (Std. 488.2-1987). All status including the option complement are available remotely.

Interface Functions Supported: SH1, AH1, T5, TE0, L3, LE0, SR1, RL1, PP0, DC1, DT1, C0, and E2.

### INTERNAL MODULATION SOURCE (Sine Wave)

Rates: 0.1 Hz to 200 kHz, key-selectable 400/1000 Hz

Display Ranges: 00.1 to 99.9 Hz

100 to 999 Hz

1.00 to 9.99 kHz

10.0 to 99.9 kHz

100 to 200 kHz

Frequency Resolution: 0.1 Hz or 3 digits

Frequency Accuracy: Same as reference oscillator  $\pm 7$  millihertz

Table 1-1. Specifications for Model 6082A (cont)

**Output Level Range:** 0 to 4V pk into 600 $\Omega$

**Output Level Resolution:** 1 mV pk or 3 digits, whichever is greater.

**Distortion:** <0.15% THD for output levels >0.2V pk and modulation frequency <20 kHz.

**Output Level Accuracy:**  $\pm(4\% + 15 \text{ mV})$  for modulation frequency <100 kHz.

**Output Impedance:** 600 $\Omega \pm 2\%$

**Other Waveforms Available by Special Function:**

- Square Wave (Special Function 752)
- Triangle Wave (Special Function 751)
- Pulse (Special Functions 758,759), width 100 ns to 1/Fmod in 100 ns or 3-digit increments, whichever is greater. Rate and width are coherent with signal generator time base.

#### EXTERNAL MODULATION

1V pk provides indicated modulation index. Nominal input impedance is 600 $\Omega$ . Maximum level is  $\pm 5\text{V}$  pk.

#### MODULATION MODES

Any combination of AM, PULSE, and FM or  $\emptyset$ M, internal or external, may be used.

#### DIGITAL FREQUENCY SWEEP

**Sweep Modes:** Auto, single, or manual

**Adjustable Parameters:** Sweep symmetry, sweep speed, sweep width, and sweep increment.

**Sweep Speed:** Minimum 40 ms/increment selectable as (minimum + dwell time) where dwell time can be 0, 20, 50, 100, 200, or 500 ms, or 1, 2, 5, or 10s at each increment.

#### DIGITAL AMPLITUDE SWEEP

**Sweep Type:** Linear (volts) or logarithmic (dB)

**Sweep Modes:** Auto, single, or manual.

**Adjustable Parameters:** Sweep symmetry, sweep speed, sweep width, and sweep increment.

**Sweep Speed:** Minimum 30 ms/increment selectable as (minimum + dwell time) where dwell time can be 0, 20, 50, 100, 200, or 500 ms, or 1, 2, 5, or 10s at each increment.

#### SWEEP OUTPUT (AUX Connector Pin 5)

0 to +10V $\pm 10\%$ , up to 4096 points in a stepped ramp, load >2 k $\Omega$ .

#### PEN LIFT OUTPUT (AUX Connector Pin 4)

TTL level, high during sweep retrace, load >2 k $\Omega$ .

#### GENERAL SPECIFICATIONS

**Temperature:** Operating, 0 to +50 $^{\circ}\text{C}$  (+32 to +122 $^{\circ}\text{F}$ ).

Nonoperating, -40 to +75 $^{\circ}\text{C}$  (-40 to +167 $^{\circ}\text{F}$ ).

**Operating Humidity Range:** 95% to +30 $^{\circ}\text{C}$ , 75% to +40 $^{\circ}\text{C}$ , and 45% to +50 $^{\circ}\text{C}$ .

**Operating Altitude:** Up to 10,000 ft.

**Vibration:** Nonoperating, 5 to 15 Hz at 0.06 in, 15 to 25 Hz at 0.04 in, and 25 to 55 Hz at 0.02 in, double amplitude (DA).

**Shock:** Nonoperating, bench handling per MIL T 28800C Class 5, Style E.

**Electromagnetic Compatibility:** The radiated emissions induce <0.5  $\mu\text{V}$  (at RF carrier frequency) into a 1-inch diameter, 2-turn loop, 1-inch from any surface as measured into a 50 $\Omega$  receiver.

## INTRODUCTION AND SPECIFICATIONS

Table 1-1. Specifications for Model 6082A (cont)

### Complies with Standards:

- CE03 of MIL-STD-461B (Power and interconnecting leads), 0.015 to 50 MHz.
- RE02 of MIL-STD-461B (14 kHz to 10 GHz).
- FCC Part 15, Class B.
- VDE 0871B
- CISPR 22

<b>Size:</b>	<b>Width</b>	<b>Height</b>	<b>Depth</b>
	43 cm	13.3 cm	59.7 cm
	17 in	5.25 in	23.5 in

**Power Requirements:** 100, 120, 220, or 240V, each  $\pm 10\%$ ; 48-63 Hz; 200 VA, <15 VA in standby, with any options installed.

**Weight:** 30 kg (65 lbs).

### OPTION -130 HIGH-STABILITY REFERENCE

**Aging Rate:**  $\leq 5 \times 10^{-10}$ /day, after 21 days continuous operation.

**Temperature Stability:**  $\leq 2 \times 10^{-10}$ /°C. (Oven remains powered in standby.)

### OPTION -132 MEDIUM-STABILITY REFERENCE

**Aging Rate:**  $\leq 1 \times 10^{-7}$ /month after 5 days continuous operation.

**Temperature Stability:**  $\leq 1 \times 10^{-7}$  (0 to +50°C)

### OPTION -830 REAR PANEL CONNECTORS

Moves connectors for MODULATION INPUT, MOD output, and RF OUTPUT to the rear panel. The front panel connector locations are covered with plugs.

### SUPPLEMENTAL CHARACTERISTICS

The following characteristics are provided to assist in signal generator applications, and to describe some other aspects of typical performance.

**Frequency Switching Speed:** <100 ms to settle within 100 Hz

**Amplitude Switching Speed:** <100 ms to settle within 0.1 dB

**Pulse Modulation Delay:** 80 ns typical

## Section 2 Theory of Operation

### INTRODUCTION

2-1.

This section begins with a description of how the functional blocks of the Signal Generator operate and how the functional blocks interrelate. Detailed circuit descriptions presented in Section 6 expand on the theory discussion.

Theory of operation is presented in the following three major topics:

1. General Description

Briefly describes the Signal Generator's main functional sections.

2. Functional Description

Describes functional blocks of the Signal Generator and how they relate to the main output parameters: frequency, amplitude, and modulation.

3. Digital Controller Software Description

Gives an overview of the software and how it controls the hardware.

### GENERAL DESCRIPTION

2-2.

The 6082A Synthesized RF Signal Generator is made up of the following four major sections:

1. The Front Panel section includes the display and keyboard for local operator interface control, including the primary controls, various external connectors, and indicators. All front panel keys and displays (except the main power switch) are monitored and handled by the A13 Controller PCA, which is housed in the output module.
2. The Synthesizer Module section includes four pca's that generate synthesized RF signals phase locked to a reference standard. The module also houses the modulation oscillator, which is the modulating source for internal AM, FM,  $\phi$ M, and pulse.

## THEORY OF OPERATION

3. The Output Module section includes circuitry to further refine and process synthesized RF signals. Included is circuitry for properly programming frequency, modulation, and level control. Digital control circuits, including the Controller PCA, are also housed in this module.

### NOTE

*The Synthesizer and Output module sections house the circuit boards that generate the instrument output signal. These metal, multi-compartmented enclosures shield the circuits, provide an isolation barrier to spurious signals, and isolate circuitry from the outside environment.*

4. The Rear Panel section includes the power supply, cooling fan, various external connectors, fuse holder, and line voltage selector.

## FUNCTIONAL DESCRIPTION

2-3.

The functional description provides a general overview of the major circuit blocks in the Signal Generator. This description explains how the blocks relate to one another, how they are controlled, and how they generate or use signals. Refer to Section 6, Troubleshooting and Repair, for component-level theory of operation.

The functional blocks of the Signal Generator described in this section are listed below:

- Frequency
- Frequency Modulation
- Internal Modulation Oscillator
- Phase Modulation
- Level Control
- Amplitude Modulation
- Pulse Modulation
- Power Supply
- Digital Controller Software Description

## Frequency

2-4.

The output frequency ( $F_o$ ) is programmable, with 1-Hz resolution, from 100 kHz to 2112 MHz. The band controls are programmed in eight bands determined by the output frequency ( $F_o$ ). A coarse loop and subsynthesizer frequency are determined for each output frequency.

The coarse loop frequency and the instrument-specific compensation data determine the programming of the coarse loop steering digital-to-analog converter (dac), compensation dac, and voltage controlled oscillator (vco) control bits.

The subsynthesizer frequency and the instrument-specific compensation data determine the programming of the subsynthesizer compensation dac.

The output frequency and the instrument-specific compensation data generate the programming of the sum loop steering and compensation dac's.

The 100-kHz to 2112-MHz frequency coverage is divided into the eight bands shown in Table 2-1.

Table 2-1. Frequency Coverage Bands

BAND	FREQUENCY COVERAGE (MHz)
HET	0.1 to 14.999999
Divide-by-32	15 to 31.999999
Divide-by-16	32 to 63.999999
Divide-by-8	64 to 127.999999
Divide-by-4	128 to 255.999999
Divide-by-2	256 to 511.999999
Fundamental	512 to 1055.999999
X2	1056 to 2112

The Sum Loop VCO assembly produces a signal that ranges from 480 to 1056 MHz. This signal is divided by factors of 2 to produce the bands shown in Table 2-1. The HET band is produced by mixing 80.1 to 94.999999 MHz (from the Divide-by-8 band) with 80 MHz to produce 0.1 to 14.999999 MHz.

Three signals are combined in the Sum Loop PCA: the output of the Sum Loop VCO, the Coarse Loop output signal, and the 80 MHz signal from the FM PCA. These signals are combined as follows.

The first mixer combines the Sum Loop VCO PCA output (at the fundamental frequency, 480 to 1056 MHz) with the Coarse Loop frequency (576 to 960 MHz in 8 MHz steps) to produce a signal of 88 to 96 MHz. This signal is subsequently mixed with the 80 MHz signal from the FM PCA to produce 8 to 16 MHz. This 8 to 16 MHz signal is compared with an 8 to 16 MHz signal in 0.5 Hz steps that is derived on the Subsynthesizer VCO PCA. The comparison results in a dc control voltage that locks the loop.

If the Sum Loop output frequency is below 760 MHz, the FM and Subsynthesizer signals are subtracted from the Coarse Loop signal. If the Sum Loop output frequency is above 760 MHz, the FM and Subsynthesizer signals are added to the Coarse Loop signal.

The A2 Coarse Loop PCA contains the reference circuits and generates a 576-to 960-MHz signal in 8-MHz steps. The main reference frequency for the Signal Generator is a 40-MHz crystal oscillator. This oscillator is phase locked to either an internal 10-MHz TCXO or to an external reference. Either a 10-MHz (default) or an alternate 5-, 2-, or 1-MHz external reference may be selected by special function. (The setting of 5-, 2-, or 1-MHz for the alternate external reference is selectable by setting a switch on the Coarse Loop PCA. Its default is 5 MHz.) The Coarse Loop PCA doubles the 40-MHz reference frequency to 80 MHz. This frequency is the local oscillator for the HET band and is divided to 20 MHz for use as the reference for the A14 FM PCA.

The Coarse Loop generates the 576- to 960-MHz signal using a combination of phase lock and delay line discriminator frequency control circuitry to produce a low phase noise signal. The delay line is a 125-ns cable contained in the module.

## THEORY OF OPERATION

The Subsynthesizer generates a 16- to 32-MHz signal with 1 Hz resolution. This is further divided on the Sum Loop PCA to 8 to 16 MHz. The subsynthesizer generates fine frequency steps using a modified N-divider loop with a single-sideband (SSB) mixer in the feedback path.

The reference frequency for the loop is 1 MHz, which would normally provide 1-MHz steps in a conventional N-divider loop. However, by using pulse deletion, which is controlled by a rate multiplier, the resolution is extended to 10 kHz. Additional resolution is gained by introducing a 10- to 20-kHz signal in a SSB mixer. This signal is produced by a gate array, which contains a 14-bit rate multiplier.

The A14 FM PCA generates an 80-MHz signal that can be frequency modulated.

### Frequency Modulation

2-5.

The output signal is modulated by either the internal modulation oscillator or an external frequency source. Modulation rates can be varied from dc to 200 kHz, and the following modes of frequency modulation can be selected:

- Normal ac FM

Bandwidth from 20 Hz to 200 kHz.

- Low-rate FM

Certain applications require FM at very low modulation rates but cannot accept the FM loop unlocked condition associated with the dc FM mode. Bandwidth is enabled down to 0.5 Hz, however, maximum deviations are limited.

- DC FM

This mode allows the RF output signal to be frequency modulated by a dc signal. Maximum deviations can still be realized; however, the modulation loop oscillator is not locked to the Signal Generator's main timebase. When dc FM is enabled, the FM oscillator's center frequency (80 MHz) is set to the previously locked center frequency ( $\pm 1$  kHz) by an automatic zeroing circuit in conjunction with a software routine. This search for an FM loop correction voltage is called a dc FM cal cycle. The front panel displays the word "PAUSE" during this time. The time required to perform a cal cycle is determined by the internally selected FM deviation band (deviations in excess of 250 kHz can take a cal cycle up to 5 seconds). While dc FM is enabled, the RF output frequency slowly drifts with time.

- Low-distortion mode

This mode provides the optimum phase noise-to-distortion performance at 3.5 kHz FM deviation at modulation frequencies of 300 Hz to 3 kHz.

Refer to Section 6E for more detailed information about frequency modulation.

Frequency modulation (FM) is programmable to three digits of resolution through six deviation ranges. The maximum programmable FM deviation depends on the RF frequency output. Deviation up to 4 MHz is possible (see Table 2-2, FM Band Limits) on the high RF band. The input modulating signal is level programmed using a 12-bit FM dac and then routed through two different paths for correct ranging. The two paths, high rate and low rate, are required for flat frequency response. These modulating signals are then summed into a phase-locked loop (PLL) circuit.

Table 2-2. FM Band Limits (Normal AC-Coupled FM Mode)

FREQ BAND FM BAND	1056 to 2112 MHz	512 to 1056 MHz	256 to 512 MHz	128 to 256 MHz	64 to 128 MHz and 0.1 to 15 MHz	32 to 64 MHz	15 to 3 MHz
6	8.00 MHz 2.10 MHz	4.00 MHz 1.01 MHz	2.00 MHz 501 kHz	1.00 MHz 251 kHz	500 kHz 126 kHz	250 kHz 62.6 kHz	125 kHz 31.3 kHz
5	2.00 MHz 501 kHz	1.00 MHz 251 kHz	500 kHz 126 kHz	250 kHz 62.6 kHz	125 kHz 31.3 kHz	62.5 kHz 15.7 kHz	31.2 kHz 7.82 kHz
4	500 kHz 126 kHz	250 kHz 62.6 kHz	125 kHz 31.3 kHz	62.5 kHz 15.7 kHz	31.2 kHz 7.82 kHz	15.6 kHz 3.91 kHz	7.81 kHz 1.96 kHz
3	125 kHz 31.3 kHz	62.5 kHz 15.7 kHz	31.2 kHz 7.82 kHz	15.6 kHz 3.91 kHz	7.81 kHz 1.96 kHz	3.90 kHz 977 Hz	1.95 kHz 489 Hz
2	31.2 kHz 7.82 kHz	15.6 kHz 3.91 kHz	7.81 kHz 1.96 kHz	3.90 kHz 977 Hz	1.95 kHz 489 Hz	976 Hz 245 Hz	488 Hz 123 Hz
1	7.81 kHz 0 Hz	3.90 kHz 0 Hz	1.95 kHz 0 Hz	976 Hz 0 Hz	488 Hz 0 Hz	244 Hz 0 Hz	122 Hz 0 Hz
0	CW MODE						

The PLL circuit is made up of four major sections: an 80-MHz oscillator, two programmable dividers, two selectable phase detectors, and a loop amplifier. These circuits, including the two modulating signal paths, are located on the A14 FM PCA.

The first of these sections is the 80-MHz oscillator. The 80-MHz FM oscillator has two selectable deviation modes to cover the deviation ranges. These deviation modes are:

1. The low (low noise) deviation mode. In this mode the oscillator runs in the high-Q mode.
2. The high-deviation mode. In this mode the tuning sensitivity of the oscillator is increased causing a higher level of phase noise. A linearizer circuit is added to the loop at higher deviation ranges to maintain low distortion.

The second PLL section consists of two programmable divider networks. These networks supply the needed frequencies for the phase detectors. One network divides the reference frequency while the other network divides the oscillator frequency. Both frequencies are divided by a predetermined amount depending on the FM mode and deviation range.

## THEORY OF OPERATION

The third PLL section consists of two selectable phase detector circuits. Only one of two phase detectors is active at any time. One of these is a standard dual flip-flop phase detector used in low deviation bands. The other is a N-PI phase detector (that uses a up/down counter and a dac), which allows a large amount of deviation at low modulating rates. The phase detectors produce output signals that are related to the phase relationship of the divided FM oscillator to the divided reference frequency. The output is then applied to the loop amplifier.

The fourth section in the PLL circuitry. The loop amplifier forms Control circuits select the loop amplifier's feedback path to control the phase-locked bandwidth. The output of the amplifier feeds through a low-pass filter before completing the loop back to the 80-MHz oscillator as the loop-control voltage.

### Internal Modulation Oscillator

2-6.

The modulation oscillator operates as either a direct digital synthesizer (DDS) or as a pulse generator. Both functions are implemented in a custom integrated circuit and are synthesized from the main reference frequency source of the Signal Generator.

The DDS is the modulating source for internal AM, FM, and  $\phi$ M. It can digitally synthesize sine, triangle, and square waveforms at a specified modulating frequency.

The DDS wave generator frequency can be varied from 0.1 Hz to 200 kHz at a resolution of 0.1 Hz. The oscillator is based on an algorithmic wave generation method. This method provides a very accurate and stable signal source of high purity and low harmonic distortion level. The waveform data generated by the algorithm is stored in two EPROMs.

As mentioned earlier, the modulation oscillator can also be configured as a pulse generator whose pulse width and repetition rate are programmable. In the pulse generation mode, frequency can be programmed from 10 Hz to 200 kHz, which results in a pulse period of 100 ms through 500  $\mu$ s. The pulse width can be set from 100 ns to 100 ms with a resolution of 100 ns.

The modulator oscillator output signals are available at the front panel MOD OUTPUT BNC connector.

Refer to Section 6F for more information about the internal modulation oscillator.

### Phase Modulation

2-7.

Phase modulation ( $\phi$ M) is programmable with three digits of resolution in six ranges. Phase modulation is internally normalized to 10 kHz, then programmed as FM deviation. The  $\phi$ M index is multiplied by 10 kHz (regardless of the modulation frequency) to get the equivalent FM deviation. Refer to Table 6E-2 (Section 6E) to determine the FM dac and range settings from this equivalent FM deviation.

The maximum programmable phase modulation deviation is dependent on the RF output frequency. Regardless of the output frequency, phase modulation deviations up to 800 radians may be entered. However, the STATUS indicator blinks and the FM dac clamps at full scale if the entry is beyond the allowed upper limit for that frequency band. The maximum programmable phase modulation deviation in each frequency band is listed in Section 4C of the Operator Manual.

Phase modulation is achieved by reconfiguring the modulation circuits to cause a true phase modulation response for both internal and external modulation inputs. The display is correspondingly changed to indicate deviation in radians. Two modes are available: large deviation at a limited bandwidth and limited deviation for a higher rate bandwidth.

### **Output/Level Control**

**2-8.**

Two separate circuits provide output/level control: a step attenuator and a vernier level dac. The A35 Attenuator/RPP Assembly provides coarse level control in 6.02-dB steps. Fine level control is provided by a vernier level dac (level-control multiplying dac) that varies the leveling-loop control voltage. The controller microprocessor automatically controls the step attenuator and the multiplying factor of the vernier level dac so that it corresponds to the programmed signal level. The multiplying factor also includes level correction information to compensate for the Signal Generator frequency response.

Level correction data for both the A31 Output PCA and the A35 Attenuator/RPP Assembly is stored in the compensation memory located on the A13 Controller PCA. The level correction data is based on measurements taken of each assembly during level compensation of the Signal Generator.

The level correction data is applied only to the vernier level dac and does not affect the coarse level control provided by the Attenuator/RPP Assembly. In other words, all Signal Generators have the same attenuator pads inserted at a selected level even though the correction data differs for each Signal Generator.

To improve level accuracy in relation to temperature, the Signal Generator software compensates for temperature variations. This method of compensation relies on data that remains constant for all Model 6082A Signal Generators.

### **Amplitude Modulation**

**2-9.**

A 12-bit multiplying AM dac programs the amplitude modulation depth from 0 to 99.9% with 0.1% resolution. A nominal setting of 3330 on the AM dac corresponds to 99.9% AM depth.

The AM dac receives a 1V peak modulating signal from the internal modulation oscillator or from the external MOD INPUT connector. The A13 Controller PCA calculates the multiplying factor of the dac signal and sums it with a fixed dc reference voltage. The multiplying factor of the dac corresponds to the programmed percentage of modulation.

The dc-plus-modulation composite signal is then summed with the leveling loop-control voltage of the level dac. The automatic level control (ALC) circuitry modulates the RF signal's amplitude by forcing the RF amplitude to track the loop-control voltage.

Refer to Section 6D for more information about amplitude modulation.

**Pulse Modulation**

**2-10.**

Two single-pole double-throw GaAs FET switches located at the input to the output amplifier act as a pulse modulator, and are also used for signal routing for het band operation. These switches are controlled by the internal modulation oscillator or by an external signal, and provide a very fast, high ON/OFF ratio RF pulse.

**Power Supply**

**2-11.**

The power supply provides +15V, -15V, +5V, +37V, +30V, +24V, +23.4V dc, and 6V ac to the Signal Generator. All the supplies are series-pass regulated except the 6V ac display-filament supply. A fuse/filter/line-voltage selector allows the Signal Generator to operate from 100, 120, 220, or 240V ac.

Refer to Section 6A for more information about the power supply.

**DIGITAL CONTROLLER SOFTWARE DESCRIPTION**

**2-12.**

A 68HC000 microprocessor located on the A13 Controller PCA executes the Signal Generator software, which is stored in 512K bytes of ROM. The program stack and RAM variables are stored in 64K bytes of static RAM. 8K bytes of battery-backed CMOS RAM are available: 4K bytes act as a nonvolatile memory for front panel setups (instrument state memory), and 4K bytes are used for calibration/compensation data. In addition, an 8K byte EEPROM contains a redundant copy of the calibration/compensation data. The Controller PCA software performs the following general functions:

- Services the front panel and the IEEE-488 Interface.
- Configures the hardware to produce the required output then applies calibration and compensation data to optimize the performance.
- Implements a set of self test and diagnostic functions.

Refer to Section 6B for more detailed information about the digital controller.

**User Interface**

**2-13.**

The software operating system allows several tasks to operate in a round-robin fashion. Input and output to both the front panel and the IEEE-488 Interface execute at a higher priority and are handled as interrupt routines.

At power-on, the software performs a self test and initializes both the RAM and the RF hardware. Four tasks are continuously in operation:

- Diagnostic service task
- Front panel key task
- Knob task
- IEEE-488 task

The diagnostic service task monitors the instrument status signals. The front panel key task, knob task, and IEEE-488 task process user input. A fifth task controls the RF output when a frequency or amplitude sweep is active. A sixth task is activated only when needed to process certain STATUS (out-of-range or malfunction) or REJ ENTRY (rejected entry) conditions that cause the display to flash. A seventh task is activated when the automatic user compensation procedures have been initiated.

### **Calibration/Compensation Memory**

**2-14.**

The calibration/compensation memory contains the instrument-specific compensation data for the coarse loop compensation dac, coarse loop steering dac, sum loop compensation dac, sum loop steering dac, subsynthesizer compensation dac, the Output assembly, and the Attenuator/RPP Assembly. In addition, the calibration/compensation memory stores the AM, FM, level, and reference oscillator calibration data. Since the integrity of this data is crucial to the performance of the Signal Generator, redundant copies of the data are kept in two separate nonvolatile memory ICs.

Hardware and software protection schemes guard against accidental erasure of calibration/compensation data. The rear panel switch (labeled CAL|COMP) must be set to the 1 (ON) position before updating the calibration/compensation memory.

The calibration/compensation memory self test verifies the CRC checksums of each data segment. A detailed report of the compensation memory status can be interrogated from the front panel or the IEEE-488 interface. If the self-test detects errors, the Signal Generator uses only the valid data segments. See Appendix F for the compensation memory status codes.

### **Self Test**

**2-15.**

The Signal Generator automatically performs a self test of all circuits at power-on. If the instrument fails any of these self tests, the test results automatically display as error codes. Several special functions are available for additional tests. (See "Self Test Description" in Section 6.) Also, the microprocessor continuously monitors hardware status signals. (See Appendix E for self test codes.)

### **Status Signals**

**2-16.**

Software continuously monitors the status of the rear panel REF EXT/INT reference switch. Depending on the position of this switch, the EXTREF annunciator on the front panel lights or stays off, and the Signal Generator configures itself for internal or external reference.

The RF output of the Signal Generator is usable, but it is not necessarily calibrated if the STATUS indicator is steadily lit. The STATUS indicator blinks on and off to indicate an unusable output due to a severe overrange condition or a circuit failure. See Appendices C and D for a listing of rejected entry and STATUS codes.

## Section 3 Performance Tests

### INTRODUCTION

3-1.

The information in Section 3 describes the performance tests for the key parameters of the Model 6082A Synthesized RF Signal Generator.

The Signal Generator specifications as listed in Section 1 are used as the performance standard. These closed-case performance tests may be used as:

- An acceptance test upon receipt of the instrument.
- An indication that repair and/or calibration is required.
- A performance verification after completing repairs or calibration of the instrument.

Individual performance tests can also be used as troubleshooting aids.

Warm up the Signal Generator being tested, called the UUT for Unit Under Test throughout this section, with all covers in place for at least two hours before beginning the performance tests.

Fluke recommends that closed-case calibration (as described in Section 4) be performed at 2-year intervals.

### TEST EQUIPMENT

3-2.

Table 3-1 lists the recommended test equipment for performance testing, adjustment procedures, and for troubleshooting the Signal Generator. A two-turn loop is shown in Figure 3-1.

### POWER-ON TEST

3-3.

Every time you turn on the power, the 6082A executes built-in self test routines.

#### REQUIREMENT:

The Signal Generator must successfully pass the self test.

PERFORMANCE TESTS

Table 3-1. Recommended Test Equipment

INSTRUMENT NAME	MINIMUM REQUIREMENT	MANUFACTURER DESIGNATION	NOTES 1
DVM	5 1/2-Digit, 0.3% dc to 20 kHz	JF 8840A-09	A,P
DMM	3 1/2-Digit, 1% dc and 1 kHz	JF 8020B	A,P,T
RMS Voltmeter	10 Hz to 20 MHz, low noise	JF 8922A	
Wideband Amplifier	>25-dB gain, 0.1 to 1300 MHz NF < 9 dB.	HP 8447D-010	P
RF Spectrum Analyzer	0.1 to 2.9 GHz	HP 71100A	P,T
Oscilloscope	Four-trace 300 MHz, 5-mV/Div	TEK 2465-11	T,P
FET Probe	DC to 900 MHz	TEK 6201	T
500Ω Probe	DC to 3.5 GHz, 10X	TEK P6156	T,A
RF Voltmeter	0.01 to 700 MHz, 0.01 to 3V +/- 10%	HI RF 801	T 2
Frequency Counter	0.1 to 1050 MHz; 10 Hz res; 0.1V	JF 7220A	A,P,T
Modulation Analyzer	Input: 0.15 to 1300 MHz, 0 to +20 dBm AM: 10 to 90%, +/- 1%, FM: 0.1 to 100 kHz dev +/- 1%, External LO capability	HP 8901A w/Option -003	A,P,T
Distortion Analyzer	1 to 10% range, +/- dB, 400 Hz and 1 kHz	HP 339B	A,P,T
Power Meter	Instrumentation accuracy < +/- 1%	HP 436A	A,P,T
Power Sensor (High Level)	-30 to 20 dBm; VSWR < 1.2 for 0.4 to 1 MHz, < 1.1 for 1 to 2000 MHz, < 1.3 for > 2000 MHz	HP 8482A	
Power Sensor (Low Level)	-67 to -20 dBm; VSWR < 1.4 for 10 to 30 MHz < 1.15 for 30 to 2100 MHz	HP 8484A

3. Two-Turn, 1-inch diameter loop made of #18 enamel wire soldered to a BNC connector.			
4. VSWR verified and actual attenuation calibrated to +/- 0.2 dB by the operator at application frequencies.			

Figure 3-1. Two-Turn Loop

**REMARKS:**

Two self test routines are available. One test is the normal power-on self test (also invoked with SPCL 02), which does not allow RF power above -140 dBm to be present at the RF OUTPUT connector. The second test is a more complete, extended self test (invoked with SPCL 06). This extended test does allow RF levels up to -20 dBm to be present at the RF OUTPUT connector. The normal self test begins each time the Signal Generator is turned on. Press any of the FUNCTION keys or the CRL/LCL key to abort the test.

**PROCEDURE:**

1. Start the test with the power off.
2. Press the POWER switch to the ON position.

The Signal Generator automatically starts the self test. This 5 second test includes lighting all indicators and every segment of the display.

If the Signal Generator fails any portion of the self test, failure codes appear in the four display fields. See Appendix E for an interpretation of self test status codes.

If the Signal Generator passes the self test, it automatically returns to the default state.

3. Begin the extended self test by entering SPCL 06.

The Signal Generator automatically starts the self test. This 5 second test includes lighting all indicators and every segment of the display.

If the Signal Generator fails any portion of the extended self test, failure codes appear in the four display fields. See Appendix E for an interpretation of self test status codes.

If the Signal Generator passes the self test, it automatically returns to the default state.

### **FREQUENCY ACCURACY TEST**

**3-4.**

The internal time base is compared to a frequency standard.

#### **REQUIREMENTS:**

The frequency of the UUT time base is within the specified limits.

#### **TEST EQUIPMENT:**

- Frequency standard
- Frequency counter

#### **PROCEDURE:**

1. Connect the frequency standard output to the 10 MHZ REF IN connector on the frequency counter and switch the counter to EXT REF.
2. Switch the UUT to internal reference.
3. Connect the UUT REF OUT connector to the frequency counter CHANNEL A input connector.
4. Verify that the counter displays 10 MHz  $\pm$ 10 Hz.

### **SYNTHESIS TEST**

**3-5.**

A frequency counter operating on a common reference with the Signal Generator measures the Signal Generator RF output frequency at several programmed frequencies.

#### **REQUIREMENT:**

The Signal Generator's measured and programmed frequencies agree within  $\pm 1$  count.

#### **TEST EQUIPMENT:**

- Frequency counter

#### **REMARKS:**

If the UUT fails this test, the frequency synthesis circuitry is probably at fault.

#### **PROCEDURE:**

1. Connect the UUT 10 MHz OUT to the frequency counter 10 MHz REF IN connector, and connect the UUT RF OUTPUT to the frequency counter input.

## PERFORMANCE TESTS

2. Set the UUT REF INT/EXT switch to INT.
3. Program the UUT to RCL 98.
4. Program the UUT frequency to 111.111111 MHz.
5. Program the UUT frequency step size to 111.111111 MHz.
6. Verify that the reading on the frequency counter agrees with the UUT frequency  $\pm 1$  count as the frequency is stepped from 111.111111 to 999.999999 MHz.

### HIGH-LEVEL ACCURACY TEST

3-6.

The output power is measured using a power meter at various frequencies. First the step attenuator is set for zero attenuation, then each attenuator section is individually programmed. Finally, the output level accuracy and attenuator section errors are computed.

If a measuring receiver is available for level testing, proceed directly to the Alternate Level Accuracy Test procedure further on in this section.

#### TEST EQUIPMENT:

- Power meter
- Power sensor (high level)

#### REQUIREMENT:

The output level accuracy, the attenuator section errors, and the sum of the attenuator section errors at each test frequency are:

- <  $\pm 1.0$  dB from 0.4 to 2112 MHz at  $+25 \pm 5^\circ\text{C}$
- <  $\pm 2.0$  dB from 0.1 to 0.4 MHz

#### REMARKS:

If the UUT fails this performance test, it requires calibration or repair. Possible problem areas (if no power-on status codes are present) include the A31 Output PCA, the A21 Attenuator PCA, or the A7 Relay Driver PCA.

The test frequencies of this procedure provide reasonable confidence of the amplitude accuracy of the UUT. However, additional test frequencies may be included in this test.

This test verifies the high-level accuracy of the Signal Generator and checks that the amplitude correction factors for the individual attenuator sections are correct. This high-level accuracy test, in conjunction with the mid-level accuracy and low-level accuracy tests, verifies the overall level performance of the UUT.

#### NOTE

*To test attenuator sections 4 through 7, program the 6082A Signal Generator to -12 dBm, and enter the following:*

**PROCEDURE:**

1. Calibrate and zero the power meter.
2. Program the UUT to RCL 98.
3. Connect the power sensor to the UUT RF OUTPUT.
4. Program the UUT to the levels and frequencies shown below, and verify that the errors are less than the requirement.

LEVEL	FREQUENCY
+16 dBm	0.4, 1, 5, 14, 20, 40, 80, 160, 320, 512, 550, 640 700, 850, 950, and 1055.999999 MHz
+16 dBm	0.1, 0.25, 0.399999 MHz
+13 dBm	1056, 1200, 1350, 1500, 1650, 1800, 1950, and 2112 MHz

5. Program the UUT frequency to 0.1 MHz and +12 dBm.
6. Select each attenuator section by programming the UUT amplitude to the levels shown in Table 3-2 and by using SPCL 923 through SPCL 926, and record the measured power at each level.
7. Compute the output power error for each programmed level of Table 3-2 by subtracting the programmed power in dBm from the measured power in dBm. These errors must not exceed the requirement stated above.

**Table 3-2. High-Level Accuracy Test Conditions**

ATTENUATION SECTION NOMINAL		OUTPUT POWER		ERROR (dB)	SECTION ERROR (dB)	LIMIT (dB)
		PROGRAMMED LEVEL (dBm)	MEASURED POWER (dBm)			
0	0	+12	M0	M0- 12	M0 -12	See test requirements
1	6	+6	M1	M1-6	-M0+M1+6	
2	12	0	M2	M2-0	-M0+M2+12	
3	24	-12	M3	M3-12	-M0+M3+24	
4	24	-12	M4	M4-12	-M0+M4+24	
5	24	-12	M5	M5-12	-M0+M5+24	
6	24	-12	M6	M6-12	-M0+M6+24	
7	24	-12	M7	M7-12	-M0+M7+24	
					Sum of Errors	

## PERFORMANCE TESTS

8. Subtract the measured power for section zero from the sum of the measured power for that section plus the nominal attenuation for that section. This is done for attenuator sections 1 through 7 only. (Example,  $(-M_0+M_1+6)$  for section 1.) The eight section errors and their sum must not exceed the requirement. Table 3-3 shows the parameters of the high-level accuracy test.

Table 3-3. High-Level Accuracy Test Conditions Sample

ATTENUATION SECTION NOMINAL		OUTPUT POWER		ERROR (dB)	SECTION ERROR (dB)	LIMIT (dB)
		PROGRAMMED LEVEL (dBm)	MEASURED POWER (dBm)			
0	0	+12	+12.2	+0.2	+12.2-12.0	= +0.2
1	6	+6	+05.9	-0.1	-12.2+5.9+6	= +0.3
2	12	0	-00.1	-0.1	-12.2-0.1+12	= -0.3
3	24	-12	-12.1	-0.1	-12.2-12.1+24	= -0.3
4	24	-12	-11.8	+0.2	-12.2-11.8+24	= +0.0
5	24	-12	-12.0	+0.0	-12.2-12.0+24	= -0.2
6	24	-12	-12.1	-0.1	-12.2-12.1+24	= -0.3
7	24	-12	-11.9	+0.1	-12.2-11.9+24	= -0.1
					Sum of Errors	= -0.7

9. Repeat steps 4 through 7 with the UUT programmed to each of the following frequencies:

1, 5, 14, 20, 40, 80, 160, 320, 550, 640, 700, 850, 950, 1056, 1300, 1600, 1900, and 2112 MHz

Table 3-3 is an example of this procedure in which the measured power and the error calculations are shown. This example is for one frequency, and these measurements and calculations are repeated at other frequencies. In this case, the section errors and the sum of the section errors are within the test limits; therefore, the unit passed the high-level accuracy test.

### MID-LEVEL ACCURACY TEST

3-7.

The level accuracy is verified using a power meter with a low-level power sensor. This verification is done from -24 to -66 dBm at frequencies of 10, 14, 20, 40, 80, 160, 320, 550, 640, 700, 850, 950, 1056, 1300, 1600, 1900, and 2112 MHz.

#### REQUIREMENT:

Amplitude accuracy is:

$< \pm 1.0$  dB from 10 to 2112 MHz @  $+25 \pm 5^\circ\text{C}$

**TEST EQUIPMENT:**

- Power meter
- Power sensor (low level)

**REMARKS:**

The mid-level accuracy test, in conjunction with the high-level accuracy test and the low-level accuracy test, verifies the overall level performance of the UUT.

If the UUT fails this test after passing the high-level accuracy test, problems with the A21 Attenuator PCA or the A7 Relay Driver PCA are indicated.

Use the UUT RF OUTPUT ON/OFF control when zeroing the power meter.

**PROCEDURE:**

1. Program the UUT to RCL 98, 10 MHz, and -24 dBm.
2. Calibrate the power meter.
3. Zero the power meter.
4. Connect the power meter and power sensor to the UUT RF OUTPUT.
5. Measure the UUT output power (in dBm) with the power meter. The output should agree with the programmed level to the Amplitude Accuracy Requirement.
6. Repeat step 5 for levels of -30, -36, -42, -48, -54, -60, and -66 dBm.
7. Repeat steps 5 and 6 for frequencies of 14, 20, 40, 80, 160, 320, 550, 640, 700, 850, 950, 1056, 1300, 1600, 1900, and 2112 MHz.

**LOW-LEVEL ACCURACY TEST****3-8.**

An RF spectrum analyzer and amplifier are used to verify the UUT level accuracy at -127 dBm and -140 dBm at frequencies of 10, 14, 20, 40, 80, 160, 320, 550, 640, 700, 850, 950, 1056, 1300, 1600, 1900, and 2112 MHz.

**REQUIREMENT:**

Amplitude accuracy is:

- <  $\pm 1.0$  dB from 10 to 2112 MHz for levels to -127 dBm at  $+25 \pm 5^\circ\text{C}$ .
- <  $\pm 3.0$  dB from 10 to 2112 MHz for levels between -127 dBm and -140 dBm.

**TEST EQUIPMENT:**

- 0.1 to 1300 MHz amplifier
- 1.3 to 2.1 GHz amplifier
- 60-dB attenuator
- 13-dB attenuator
- RF spectrum analyzer
- Power meter
- Power sensor (low level)

## PERFORMANCE TESTS

### REMARKS:

The low-level test, in conjunction with the mid-level accuracy test and the high-level accuracy test verifies the overall level performance of the UUT.

If the UUT fails this test after passing the high-level accuracy test and the mid-level accuracy test a problem in the A21 Attenuator PCA, the A7 Relay Driver PCA, or a leak-around problem in the attenuator assembly is indicated. The problem may be caused by loose connectors, loose screws, damaged or misplaced gaskets, or a broken feedthrough filter.

Use the UUT RF OUTPUT ON/OFF control when zeroing the power meter.

### PROCEDURE:

1. Program the UUT to RCL 98, 10 MHz, and -67 dBm.
2. Calibrate, then connect the power meter (with low-level power sensor) to the UUT RF OUTPUT.
3. Zero the power meter.
4. With the power meter, measure the UUT output power (in dBm) and record the measurement as the variable P.
5. Connect the UUT RF OUTPUT through the 60-dB attenuator and connect the 0.1 to 1300 MHz amplifier to the input of the RF spectrum analyzer. Use well shielded cables to avoid leakage that could affect the measurement.
6. Adjust the RF spectrum analyzer to display the signal, using a resolution bandwidth of 1 kHz and a vertical display of 1 dB/Div.
7. Adjust the reference level so that the response is at a convenient reference point on the display (e.g., 2 dB below top scale). This signal response corresponds to a level of (P-A) dBm, where A is the value of the 60-dB attenuator.
8. Program the UUT to a level of -127 dBm, remove the 60-dB attenuator, and note the difference in the resulting response on the RF spectrum analyzer from the previous response (P-A). The actual UUT output level is (P-A) plus this difference and should agree with the programmed level within the requirement.
9. Repeat steps 1 through 8 adding another 13-dB attenuator (total 73 dB) to the UUT RF OUTPUT, and dial the Signal Generator level to -140 dBm. It may be necessary to reduce the spectrum analyzer resolution bandwidth.
10. Repeat steps 1 through 9 for frequencies of 14, 20, 40, 80, 160, 320, 550, 640, 700, 850, 950, and 1056 MHz.
11. Replace the 0.1 to 1300 MHz amplifier with the 1.3 to 2.1 GHz amplifier and repeat steps 6 through 9 for frequencies 1300, 1600, 1900, and 2112 MHz.

**ALTERNATE LEVEL ACCURACY TEST****3-9.**

A measuring receiver is used to verify the UUT level accuracy at various amplitude and frequency settings that test all level ranges of the UUT on all RF bands. This test is an alternate method that replaces the previous three low-level, mid-level, and high-level accuracy tests.

**REQUIREMENTS:**

Amplitude accuracy is:

- <math>\pm 1\text{ dB}</math> from 0.4 to 1055.999999 MHz from +16 to -127 dBm at  $+25 \pm 5^\circ\text{C}$
- <math>\pm 1\text{ dB}</math> from 1056 to 2112 MHz from +13 to 0 dBm at  $+25 \pm 5^\circ\text{C}$
- <math>\pm 2\text{ dB}</math> from 0.1 to 0.4 MHz from +16 to -127 dBm
- <math>\pm 3\text{ dB}</math> from 0.1 to 2112 MHz from -127 to -140 dBm

**TEST EQUIPMENT:**

- Measuring receiver
- Sensor module
- HFSSG (local oscillator type)
- 1.3 to 2.1 GHz amplifier
- Power supply
- Microwave converter

**REMARKS:**

The alternate-level accuracy test is a more comprehensive test than the high-level, mid-level, and low-level accuracy tests.

If the UUT fails this test, the UUT must be calibrated or repaired.

If the UUT fails this test at higher levels, problems with the A31 Output PCA, the A21 Attenuator PCA, or the A7 Relay Driver PCA may be indicated.

If the UUT fails this test at lower levels, a problem with the A21 Attenuator PCA, the A7 Relay Driver PCA, or an RF leakage problem with the attenuator assembly is probably indicated. The problem may be caused by loose connectors, loose screws, damaged or misplaced gaskets, or a broken feedthrough filter.

Because of operational subtleties in measuring receivers and with the intent of reducing the risk of measurement errors, the following procedure is written specifically for use with the Model HP 8902A Measuring Receiver.

**NOTE**

*The calibration factors for the sensor module must be stored into the measuring receiver's "Cal Factor" table prior to performing calibrated RF power measurements. Correctly entered cal factors can be verified on the HP 8902A by using special functions 37.5 and 37.6. (Refer to the HP 8902A manual.)*

## PERFORMANCE TESTS

### PROCEDURE (Level Measurements):

1. Connect the UUT and the measurement equipment as shown in Figure 3-2A.
2. Set the UUT REF INT/EXT switch to INT.
3. Program the UUT to RCL 98, 10 MHz, +11 dBm, and program the amplitude step to 6 dB.
4. Calibrate the measuring receiver and connect the sensor module to the UUT RF OUTPUT.
5. Verify that the level measured with the measuring receiver agrees with the UUT programmed level and is within the test requirements. Make this verification as the UUT level is stepped down from +11 dBm to -127 dBm at frequencies of 10, 120, 244, 245, 850, and 1050 MHz.
6. Verify that the level measured with the measuring receiver agrees with the UUT programmed level and is within the test requirements. Make this verification as the UUT level is stepped down from +11 dBm to -19 dBm at frequencies of 1100, 1400, 1700, and 2100 MHz.
7. Connect the UUT and the measurement equipment as shown in Figure 3-2B.
8. Program the UUT to 1100 MHz, -19 dBm, and amplitude step to 6 dB.
9. Program the HFSSG to +10 dBm and 900 MHz (200 MHz less than the UUT). Note that the reading on the measuring receiver does not agree with that of step 6 for the same frequency and level. The results obtained for the remainder of this procedure must be corrected relative to the result measured at the transfer point.
10. Verify that the level measured by the measuring receiver agrees with the UUT programmed level and is within the test requirements. Make this verification as the UUT level is stepped down from -19 to -97 dBm at each of the frequencies listed in step 6.
11. Connect the UUT and the measurement equipment as shown in Figure 3-2C.
12. Program the UUT to 1100 MHz, -97 dBm, and amplitude step to 6 dB. Note that the reading on the measuring receiver does not agree with that of step 9 for the same frequency and level. The results obtained for the remainder of this procedure must be corrected relative to the result measured at the transfer point.
13. Verify that the level measured by the measuring receiver agrees with the UUT programmed level and is within the test requirements. Make this verification as the UUT level is stepped down from -97 to -127 dBm at each of the frequencies listed in step 6.

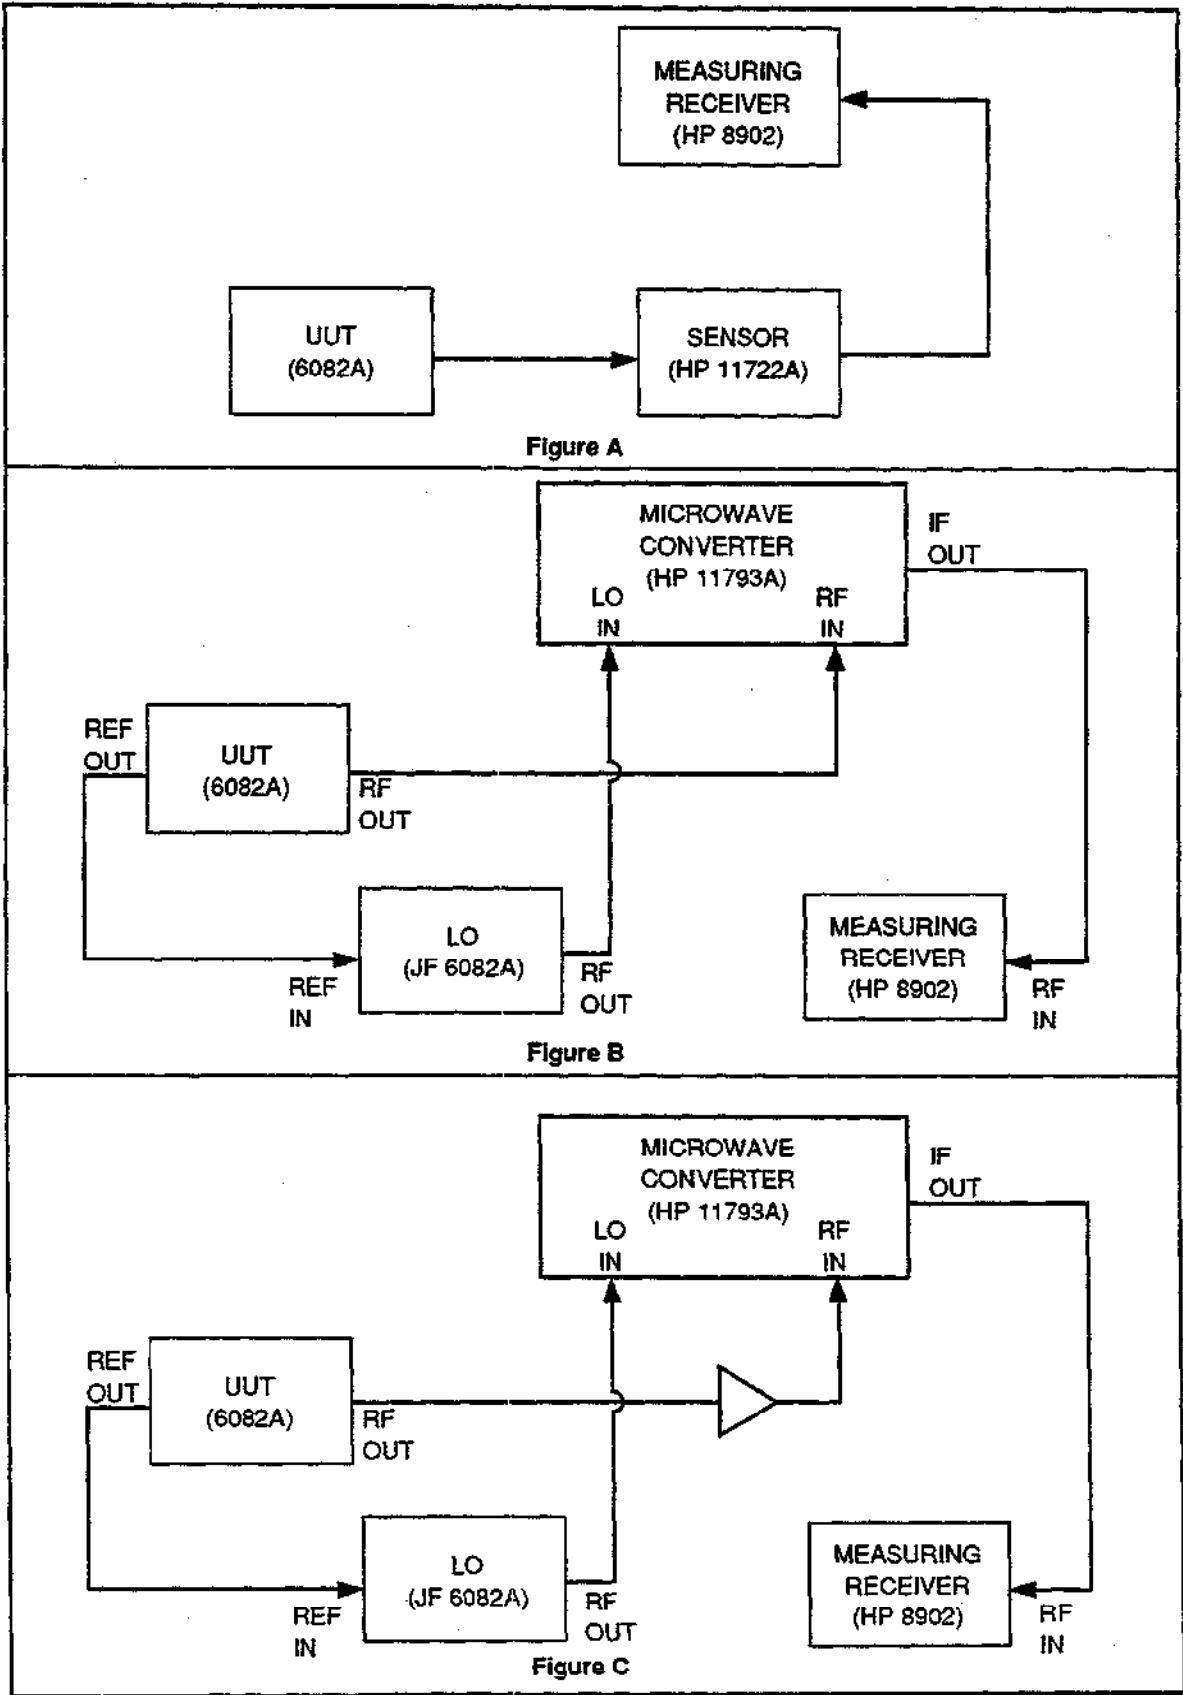

Figure 3-2. Alternate Level Accuracy Test Setup

**FLATNESS TEST**

**3-10.**

A power meter and sensor are used to verify the high level flatness of the Signal Generator.

**REQUIREMENT:**

Amplifier flatness is:

$< \pm 1.0$  dB at +10 dBm over the frequency range of 0.1 to 2112 MHz.

**TEST EQUIPMENT:**

- Power meter
- Power sensor (high level)

**REMARKS:**

If the UUT fails this test, calibration or repair is necessary. If no power-on status codes are present, likely problem areas needing repair include the A31 Output PCA, the A21 Attenuator PCA, or the A7 Relay Driver PCA.

**PROCEDURE:**

1. Calibrate and zero the power meter.
2. Connect the power sensor to the Signal Generator RF OUTPUT.
3. Program the Signal Generator to RCL 98 and then to 0.1 MHz and +10 dBm.
4. The power meter should read  $+10 \pm 1.0$  dBm.
5. Repeat step 4 for the following frequencies:
  - a. 0.2 to 2.0 MHz in 0.1 MHz steps
  - b. 2.0 to 20.0 MHz in 1.0 MHz steps
  - c. 20.0 to 200.0 MHz in 10.0 MHz steps
  - d. 200.0 to 1056.0 MHz in 20.0 MHz steps
  - e. 1056 to 2112 MHz in 40 MHz steps

**OUTPUT LEAKAGE TEST**

**3-11.**

The output signal leakage is verified using a 1-inch diameter, two-turn loop. The induced signal is measured with an RF spectrum analyzer and compared to a  $0.5\text{-}\mu\text{V}$  reference established at each reference frequency. The two-turn loop must be 1 inch away from any surface of the UUT.

**REQUIREMENT:**

Radiated emissions induce  $< 0.5 \mu\text{V}$  of the Signal Generator's output signal.

**TEST EQUIPMENT:**

- 0.1 to 1300 MHz amplifier
- 1.3 to 2.1 GHz amplifier

- RF spectrum analyzer
- Two-turn loop
- Type "N" termination
- Screen room, depending on the RF environment

**REMARKS:**

If the UUT fails this test, the problem may be caused by loose connectors, loose screws, damaged or misplaced gaskets, or a broken feedthrough filter.

**PROCEDURE:**

1. Program the UUT to RCL 98.
2. Program the UUT to 9 MHz and -113 dBm (0.5  $\mu$ V).
3. Connect the UUT RF OUTPUT to the 0.1 to 1300 MHz amplifier input, and connect the 0.1 to 1300 MHz amplifier output to the RF spectrum analyzer input. Use well shielded cables to avoid leakage that could affect the measurement.
4. Adjust the RF spectrum analyzer to display the UUT signal for a convenient reference. Make this adjustment using a vertical scale of 10 dB/division, a resolution bandwidth of 3 kHz, and a span/division of 5 kHz/division.
5. Disconnect the 0.1 to 1300 MHz amplifier from the UUT and terminate UUT output with the Type "N" termination.
6. Connect the two-turn loop to the 0.1 to 1300 MHz amplifier input.
7. Program the UUT to +13 dBm.
8. Verify that the leakage indicated by the RF spectrum analyzer is below -113 dBm (0.5  $\mu$ V) by moving the two-turn loop over the UUT surface at a distance of 1 inch.
9. Repeat steps 2 through 8 at 14, 20, 40, 80, 160, 320, 550, 640, 700, 850, 950, and 1056 MHz.
10. Program the UUT to 1300 MHz and -113 dBm.
11. Repeat steps 2 through 8, replacing the 0.1 to 1300 MHz amplifier with the 1.3 to 2.1 GHz amplifier.
12. Repeat step 11 at 1600, 1900, and 2112 MHz.

**HARMONIC, SUB-HARMONIC, AND LINE-RELATED SPURIOUS TEST 3-12.**

The Harmonic and Line-Related Spurious Test uses an RF spectrum analyzer to compare the level of the harmonic signal and close-in spurious signals to the desired signal at various programmed frequencies.

**REQUIREMENTS:**

- RF harmonics: <-30 dBc for levels  $\leq$  +13 dBm.

## PERFORMANCE TESTS

- Power line spurious signals (signals within 10 kHz of carrier): -56 dBc for frequencies less than 1056 MHz, and -50 dBc for frequencies greater than 1056 MHz.
- Subharmonics: none below 1056 MHz, and <-45 dBc above 1056 MHz.

### TEST EQUIPMENT:

- RF spectrum analyzer

### PROCEDURE:

1. Connect the UUT RF OUTPUT to the RF spectrum analyzer input.
2. Connect the RF spectrum analyzer 10 MHz output to the UUT 10 MHz input, and set the UUT to EXT REF.
3. Program the UUT to RCL 98.
4. Program the UUT to +13 dBm and 100 kHz.
5. Set the RF spectrum analyzer controls to display the UUT output signal and its harmonics (at least three harmonics wherever possible). Be careful not to overload the analyzer input. Overloading the RF spectrum analyzer causes it to generate harmonics, thus invalidating the test.
6. Verify that all the harmonics are more than 30 dB below the fundamental signal.
7. Verify that all the harmonics are more than 30 dB below the fundamental signal for the following frequencies:  
14, 20, 40, 80, 160, 320, 550, 640, 700, 850, 950, 1056, 1100, 1200, 1300, and 1400 MHz.
8. Set the RF spectrum analyzer to display the UUT output signal with a 2-kHz span and 10-Hz resolution. Verify that all spurious signals are below -56 dBc for the frequencies listed in step 7.
9. Set the RF spectrum analyzer to display the UUT output signal with a 50-kHz span and 30-Hz resolution. Verify that all spurious signals within 10 kHz of the carrier are below -56 dBc for the frequencies listed in step 7.
10. Set the RF spectrum analyzer to sweep full scan. Set the UUT RF frequency to 1056 MHz. Verify that the signal at 528 MHz ( $F_o/2$ ) and the signal at 1584 MHz ( $3 F_o/2$ ) are below -45 dBc.
11. Repeat step 10 for frequencies listed below:

FO	FO/2	3 FO/2
1200 MHZ	600 MHZ	1800 MHZ
1400 MHZ	700 MHZ	2100 MHZ
1600 MHZ	800 MHZ	2400 MHZ
1800 MHZ	900 MHZ	2700 MHZ
2000 MHZ	1000 MHZ	*
2100	1050 MHZ	*

\* Beyond the frequency range of the HP 71100

**NON-HARMONIC SPURIOUS TEST USING RF SPECTRUM ANALYZER 3-13.**

**REQUIREMENTS:**

Non-harmonic spurious signals <-100 dBc for offsets greater than 500 kHz.

**TEST EQUIPMENT:**

- RF spectrum analyzer

**REMARKS:**

An RF spectrum analyzer cannot be relied on to make -100 dBc spurious signal measurements due to the analyzer's own internal spurious signals exceeding -100 dBc at a variety of RF frequencies. A way around this is to use the spectrum analyzer in a cohered narrow span, with the spectrum analyzer reference level set 20 dB off scale. This causes the 50-dB reference line to be -70 dBc, obtaining a noise floor of -110 dBc. In this way, you can measure spurious signals of -100 dBc at offsets greater than approximately 0.5 MHz from the carrier.

**PROCEDURE:**

1. Connect the UUT RF OUTPUT to the RF spectrum analyzer input.
2. Connect the RF spectrum analyzer 10 MHz output to the UUT 10 MHz input. Set the UUT to EXT REF.
3. Program the UUT to RCL 98.
4. Program the UUT to +13 dBm, 14.9 MHz.
5. Program the RF spectrum analyzer to 5.5 MHz, reference level to -7 dBm, span to 10 kHz. Verify that the spurious signal in the center of the screen is below -100 dBc, which is more than 80 dB down from the top of the screen.
6. Program the RF spectrum analyzer and UUT to the following frequencies, and verify that the spurious signal in the center of the screen is below -100 dBc.

UUT FREQUENCY (MHZ)	RF SPECTRUM ANALYZER FREQUENCY (MHZ)
14.9	9.40
14.9	20.4
10.111111	10.999

**PERFORMANCE TESTS**

UUT FREQUENCY (MHZ)	RF SPECTRUM ANALYZER FREQUENCY (MHZ)
11	13

**PHASE NOISE, RESIDUAL FM, AND SPURIOUS TEST  
USING PHASE NOISE TEST SET**

**3-14.**

Verify spurious signals (between 10 and 100 kHz offset) and phase noise by using a LO (HFSSG) and an RF mixer to cancel the carrier providing a zero difference beat frequency. Examine this frequency for spurious signals and phase noise on a low frequency dynamic signal analyzer.

**REQUIREMENTS:**

Spurious: the spurious signals are  $< -100$  dBc for offsets  $> 10$  kHz from the carrier.

Phase Noise: as listed in Table 3-4.

Residual FM: as listed in Table 3-5.

Table 3-4. Phase Noise Requirements

APPROXIMATE CARRIER FREQUENCY BAND (MHz)	OFFSET FREQUENCY		
	1 kHz (dBc/Hz)	20 kHz (dBc/Hz)	100 kHz (dBc/Hz)
512 to 1056	-94	-131	-138
256 to 512	-100	-136	-142
128 to 256	-106	-140	-143
64 to 128	-112	-143	-144
32 to 64	-118	-143	-144
15 to 32	-124	-144	-144
0.1 to 15	-112	-137	-137

Table 3-5. Residual FM Requirements

APPROXIMATE CARRIER FREQUENCY BAND (MHz)	POST DETECTION BANDWIDTH	
	0.3 kHz TO 3 kHz (CCITT) Hz RMS	0.05 kHz TO 15 kHz Hz RMS
512 to 1056	1.5	2.0
256 to 512	0.7	1.0
128 to 256	0.4	0.5
0.1 to 128	0.2	0.4

**TEST EQUIPMENT:**

- HFSSG
- Phase noise measurement system

**PHASE NOISE AND NON-HARMONIC SPURIOUS TESTS**

This procedure uses the HP 3048A Phase Noise Test Set and an additional 6082A Signal Generator to measure the phase noise and spurious signals. The phase noise is specified at a 20-kHz offset, and the spurious signals are specified for greater than a 10-kHz offset.

By using two presumably identical generators, the measured phase noise will be 3 dB higher than each individual generator, and the measured spurious signals could be as much as 6 dB higher than each individual generator. If the measured results are within specification, both reference and UUT are within specification individually. If the measured results are out of specification, it is difficult to determine whether the reference or the UUT is out of specification without using a third 6082A. Alternatively, by using a reference generator with much better specified phase noise than the 6082A, the ambiguity can be reduced.

It is assumed that you are familiar with the operation of the HP 3048A Phase Noise Test Set. The following procedure outlines setting up the system and entering the various test parameters. Refer to the HP 3048A manual (hereafter in this procedure called the "HP manual") for more information.

**PROCEDURE:**

1. Configure the system as described in Appendix A of the HP manual.
2. Load the system software as described on pages A-10 through A-11 of the HP manual. The screen should show HP3048A PHASE NOISE SYSTEM MAIN SOFTWARE LEVEL. This screen is subsequently referred to as the main menu.
3. Connect the equipment as shown in Figure 3-3.
4. Set the reference 6082A (L input) to 1056 MHz, +17 dBm, external reference.

Figure 3-3. Phase Noise and Non-Harmonic Spurs Test Setup

5. Set the UUT 6082A (R input) as follows:
  - a. Frequency 1056 MHz
  - b. Amplitude +10 dBm
  - c. FM 2 kHz
  - d. EXT DC FM

**NOTE**

*Warm up both the UUT and reference 6082A for at least 2 hours.*

6. Select System Config. Menu. Using the Delete Instr. softkey, delete all instruments except the FFT ANALYZER and INTERFACE. Return to the main menu by selecting DONE. Be sure the address on the HP 3561 is the same as in the currently displayed menu.
7. In the main menu select Define Msrmnt. In the currently displayed menu, select Type/Range. It is not necessary to change any parameters, so select DONE.
8. Select Instr. Params. In the currently displayed menu set the carrier frequency to 1.056E9 Hz, set Detector/Discr., set Input Frequency to 1.056E9 Hz, VCO Tuning Constant to 2000 Hz/V, Center Voltage of VCO Tuning Curve 0V, Voltage Tuning Range of VCO  $\pm 1V$ , VCO Tune-port Input Resistance to 600 $\Omega$ . Phase Detector - Internal Phase Detector: 5 MHz to 1600 MHz. Select DONE to return to the Measurement Definition Menu.
9. Select Calibr Process. In the currently displayed menu select Measure the Detector Constant, Compute from expected T. Constant, and The PLL Suppression WILL be verified by using the appropriate softkey. Select DONE to return to the Measurement Definition Menu.
10. Select Source Control. In the currently displayed menu select DUT: USER'S SRCE SYSTEM CONTROL (then select CONTROL and this should change to DUT: USER'S SRCE MANUAL CONTROL), REF SOURCE: USER'S SRCE MANUAL CONTROL, TUNE VOLTAGE line to DUT, by using the appropriate softkey. Select DONE to return to the Measurement Definition Menu.

11. Select Define Graph. Change the title as appropriate. Select DONE to return to the Measurement Definition menu. Select DONE to return to the main menu.
12. To start the measurement, select New Msrmnt. Select Yes. Proceed to verify this is a new measurement. After the diagram of the setup appears on the screen, turn UUT DCFM off, then turn it on again, and select Proceed. The measurement is complete when a phase noise plot appears on the screen. To accurately measure the phase noise at 20-kHz offset, select Other Keys, then select Marker ON/OFF (which should turn the marker on). Use the knob on the keyboard to position the marker at 20 kHz. The phase noise should be below  $-130 \text{ dBc}/\sqrt{\text{Hz}}$  assuming the reference and UUT 6082A are identical. All spurs  $>10 \text{ kHz}$  offset should be below  $-100 \text{ dBc}$ . All spurs  $<10 \text{ kHz}$  offset should be below  $-56 \text{ dBc}$ .

Generate a spur list, as necessary, by selecting Computd Outputs, Spur List, List Spurs, Next Page.

If you are not measuring residual FM or  $\phi M$ , select DONE three times to return to the main menu.

Repeat for output frequencies: 14, 31, 63, 127, 255, and 511 MHz. Verify the phase noise with respect to Table 3-4.

13. Residual FM or  $\phi M$  is measured from the Computd Outputs Menu. If you are measuring residual FM or  $\phi M$  after the Spur List, select DONE, then select Integr. Noise.

To measure residual FM per the requirements in the table at the beginning of this procedure, select Data Type Snu (f) and input Start Freq. 300 Hz, Stop Freq. 3000 Hz. Select Eval. Intgrl.

Repeat for Start Freq. 50 Hz, Stop Freq. 15E3 Hz. The residual FM should be per requirements. Repeat for output frequencies: 14, 31, 63, 127, 255, and 511 MHz.

## RESIDUAL AM NOISE TEST

3-15.

Use the HP 3048A Phase Noise Test Set and an additional AM detector to measure the residual AM noise. It is assumed that the user is familiar with the operation of the HP 3048A Phase Noise Test Set. The following procedure outlines setting up the system and entering the various test parameters. Refer to the HP 3048A manual ("the HP manual") for more information.

### REQUIREMENT:

Residual AM:  $<0.01\%$  in a 50 Hz to 15 kHz post-detection bandwidth.

### TEST EQUIPMENT:

- HP 3048A Phase Noise Test Set
- HP 8472 AM Detector, polarity negative (or equivalent)
- Narda 4780-3, 3-dB pad (or equivalent)
- 300  $\mu\text{F}$ , 6V (or greater), tantalum electrolytic capacitor
- 1000 $\Omega$ , 1%,  $\frac{1}{8}$  W, metal film resistor

### PROCEDURE:

1. Configure the system as described in Appendix A of the HP manual.

## PERFORMANCE TESTS

2. Load the system software as described on pages A-10 through A-11 of the HP manual. The screen should show HP3048A PHASE NOISE SYSTEM MAIN SOFTWARE LEVEL (main menu).
3. Connect the equipment as shown in Figure 3-4.

Figure 3-4. Residual AM Noise Test Setup

4. Set the UUT 6082A as follows and warm up both the UUT and reference 6082A for at least 2 hours:
  - a. Frequency 1056 MHz
  - b. Amplitude +7 dBm
5. Select System Config. Menu. In this menu delete all instruments except the FFT ANALYZER and INTERFACE. Select DONE to return to the main menu. Be sure the address on the HP 3561 is the same as in this menu.
6. In the main menu select Define Msrmnt. In this menu select Type/Range. Select AM Noise using Next Type softkey. Return to Measurement Definition Menu by selecting DONE.
7. Select Instr. Params. In this menu set carrier frequency 1.056E9 Hz, Detector/Discr. Set Input Frequency to 1.056E9 Hz. Use Select Detect to select External Phase/AM Detector softkey. Select DONE to return to the Measurement Definition Menu.
8. Select Calibr Process. In this menu Use Next Method softkey to select Derive From Double Sided Spur. Enter Amplitude -40 dBc, Frequency 10E3 Hz. Select DONE to return to the Measurement Definition Menu.
9. Select Source Control. In this menu, use appropriate softkey to select DUT: USER'S SRCE MANUAL CONTROL, AM DETECTOR USER'S DEV. MANUAL CONTRL., and CAL SOURCE USER'S SRCE MANUAL CONTRL. Select DONE to return to the Measurement Definition Menu.
10. Select Define Graph. Change the title as appropriate. Selecting DONE to return to the Measurement Definition Menu. Select DONE to return to the main menu.

11. To start the measurement, select New Msrmnt. Select Yes, Proceed to verify this is a new measurement. After the diagram of the test setup appears on the screen, select Proceed.

When instructed to Apply Calibration spur to carrier, set the UUT to AM 2%, MOD FREQ 10 kHz, and INT AM.

When instructed to Remove calibration spur, press INT AM on the UUT (this turns off internal AM). The measurement is complete when a noise plot appears on the screen.

Select Other Keys, Computd Outputs, then Integr. Noise. Data Type should be L(f). Enter 50 Hz for Start Freq. and 15E3 Hz for Stop Freq.

Select Eval Intgrl. The noise should be below -80 dBc (0.01%).

Select DONE three times to return to the main menu.

12. Change UUT to 14 MHz. Select Define Msrmnt, then Instr. Params. Change both Carrier Frequency and Detector/Discr. Input Frequency to 14E6. Return to main menu.

13. To start the measurement select New Msrmnt. When instructed to Apply calibration spur to carrier, set the UUT to AM 2%, MOD FREQ 10 kHz, and INT AM.

When instructed to Remove calibration spur, press INT AM on the UUT (this turns off internal AM). The measurement is complete when a noise plot appears on the screen.

Select Other Keys, Computd Outputs, the Integr. Noise. Data Type should be L(f).

Enter 50 Hz for Start Freq. and 15E3 Hz for Stop Freq. Now select Eval Intgrl. The noise should be below -80 dBc (0.01%).

## MODULATION TESTS

3-16.

The following tests use a modulation analyzer to verify modulation accuracy and incidental modulation of the UUT. The modulation distortion is verified by measuring the demodulated output of the modulation analyzer with a distortion analyzer. The internal modulation oscillator frequency is measured using a frequency counter on the modulation output. The internal modulation oscillator amplitude is measured using an rms voltmeter.

### Internal Modulation Oscillator Tests

3-17.

#### REMARKS:

If the UUT fails these performance tests, calibrate and/or repair the associated circuitry.

The UUT settings in this procedure are chosen to provide strong confidence in the modulation performance of the UUT throughout its range; however, you can also check performance at other Signal Generator settings.

## PERFORMANCE TESTS

### TEST EQUIPMENT:

- Oscilloscope
- Distortion analyzer
- Frequency counter
- RMS voltmeter

### REQUIREMENTS:

Modulation Frequency Accuracy: same as reference  $\pm 7$  mHz. Output Level Accuracy:  $\pm(4\% + 15 \text{ mV})$  for rates  $< 100$  kHz, sinusoidal waveform. Sinusoidal Distortion:  $< 0.15\%$  for rates  $< 20$  kHz and level  $> 0.2\text{V pk}$ .

### PROCEDURE (Frequency):

1. Set the 6082A to internal AM modulation with 50% depth and 100 kHz RF frequency.
2. Set the modulation oscillator frequency to 10 kHz.
3. Use an oscilloscope to observe both the RF output signal and the modulation output signal on two channels.

Trigger the oscilloscope with the source. Verify that the modulation envelope appears coherent with the modulation frequency. That is, the RF signal is clearly visible within the modulation envelope (synchronized with the modulation signal).

### PROCEDURE (Distortion):

1. Connect a  $600\Omega$  load to the MOD OUTPUT connector of the 6082A.
2. Set the internal modulation oscillator to sine wave output at 2V peak and to the desired output frequency.
3. Connect the distortion analyzer, oscilloscope and rms voltmeter in parallel with the load resistor.
4. Connect the distortion analyzer to measure distortion with its low pass filter set to a frequency at least four times higher than the set modulation frequency.
5. Measure the distortion.
6. Repeat the above measurements for various modulation frequencies within the specified range.

### PROCEDURE (Level):

1. Using the JF 8922A rms voltmeter with a  $600\Omega$  termination, verify that the level of the modulation output is within the above specification.
2. Repeat the above for various frequencies and output level settings.

## NOTE

For all modulations tests, set up the test equipment as shown in Figure 3-5. The accuracy of low-deviation FM and PhiM measurements cannot be guaranteed without using a low-noise local oscillator for the modulation meter. Other tests can be done with the modulation meter's internal local oscillator. Use of the microwave converter is necessary for accurate results above 1.3 GHz. The modulation meter can be used in the 3rd overtone mode for these frequencies (see the modulation meter manual), but the accuracy cannot be guaranteed.

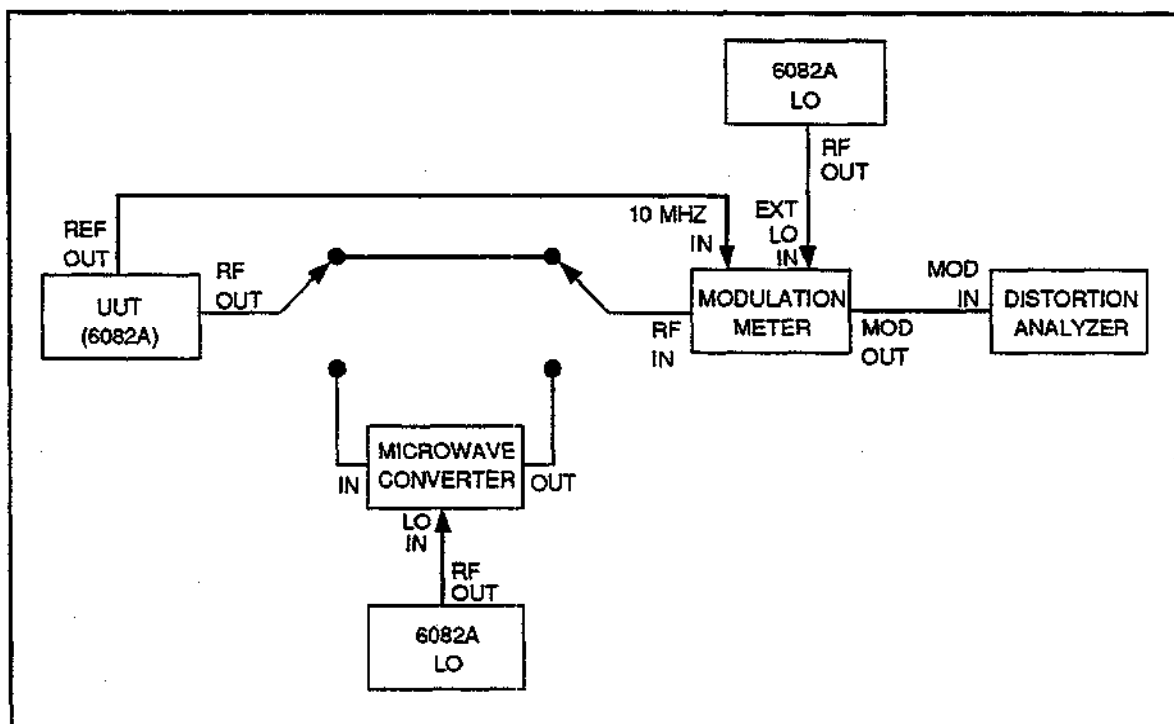

Figure 3-5. Modulation Test Setup

## Amplitude Modulation Tests

3-18.

## REMARKS:

If the UUT fails these performance tests, calibrate and/or repair the associated circuitry.

The UUT settings in this procedure are chosen to provide strong confidence in the modulation performance of the UUT throughout its range. If desired, however, performance may also be checked at other instrument settings.

## TEST EQUIPMENT:

- Modulation analyzer
- Microwave converter
- Distortion analyzer
- High-frequency synthesized Signal Generator (HFSSG)

## PERFORMANCE TESTS

### REQUIREMENTS:

AM Accuracy:  $\pm(2\% + 4\%$  of setting), up to 90% depth, 1-kHz rate.

AM Distortion at 1-kHz rate:  $<1.5\%$ , 0-30% depth,  $<3\%$ , 30-70% depth,  $<5\%$ , 70-90% depth.

AM 3-dB Bandwidth: 20 Hz to 50 kHz, ac coupled, dc to 50 kHz, dc coupled.

Incidental Phase Modulation:  $<0.2$  rad at 30% AM and 1-kHz rate.

### PROCEDURE (AM Accuracy and Distortion Test):

1. Program the UUT for a frequency of 0.2 MHz, +10 dBm level, and INT AM at 30% AM depth, and a modulation frequency of 1 kHz.
2. Connect the UUT RF OUT directly to the modulation meter RF input.
3. Connect the modulation output of the modulation analyzer to the input of the distortion analyzer.
4. Set the distortion analyzer to measure the THD of the 1-kHz modulation signal.
5. Verify that the mean AM depth  $(+PEAK + -PEAK)/2$  is between 25.5 and 34.5%.
6. Verify that the THD is less than 3%.
7. Program the remaining combinations of RF frequency, level, and AM depth listed in Table 3-6. Verify that the accuracy and distortion requirements are met.
8. Repeat steps 1 through 7 at a level of +4 dBm.
9. Insert the microwave converter between the UUT and the modulation meter and repeat steps 1 through 7 for the frequencies listed in Table 3-7.
10. Repeat step 9 at a level of +1 dBm.

### PROCEDURE (AM Bandwidth Test):

1. Program the UUT for 50% INT AM at 1 kHz rate at 100 MHz, and +10 dBm.
2. Connect the UUT RF OUTPUT directly to the modulation meter RF input.
3. With the modulation analyzer reading AM%, press the RATIO DB key to normalize the reading to 0.0 dB.
4. Set the modulation frequency to 50 kHz and read the change in level in AM in dB. Verify that the reading is above -3.0 dB.
5. Repeat steps 1 through 3 at 14, 20, 30, 40, 60, 80, 160, 250, 320, 400, 550, 640, 700, 850, 950, and 1056 MHz.

Table 3-6. AM Test Conditions

FREQUENCY (MHz)	LEVEL (dBm)	AM (%)
1056	+10	30 50 90
950	+10	30 50 90
700	+10	30 50 90
640	+10	30 50 90
550	+10	30 50 90
320	+10	30 50 90
160	+10	30 50 90
80	+10	30 50 90
40	+10	30 50 90
20	+10	30 50 90
14	+10	30 50 90

6. Repeat steps 1 through 5 at +4 dBm.
7. Insert the microwave converter between the UUT and the modulation meter.
8. Program the UUT to 1100 MHz, +7 dBm, 50% INT AM, and a 1 kHz modulation frequency.
9. With the modulation analyzer reading AM%, press the RATIO DB key to normalize the reading to 0.0 dB.

## PERFORMANCE TESTS

Table 3-7. AM Test Conditions

FREQUENCY (MHz)	LEVEL (dBm)	AM (%)
1100	+7	30 50 90
1300	+7	30 50 90
1600	+7	30 50 90
1900	+7	30 50 90
2112	+7	30 50 90

10. Set the UUT modulation frequency to 50 kHz and read the change in level in AM in dB. Verify that the reading is above -3.0 dB.
11. Repeat step 8 through 10 at 1300, 1600, 1900, and 2112 MHz.

**PROCEDURE (Incidental Phase Modulation Test):**

1. Program the UUT for 30% INT AM at 1 kHz, at 640 MHz, and +10 dBm.
2. Connect the UUT RF OUTPUT directly to the modulation meter RF input.
3. Program the modulation analyzer to measure peak phase deviation in a 0.3- to 3-kHz bandwidth. Connect the HFSSG to the external Local Oscillator input.
4. Verify that the incidental phase modulation is less than 0.2 rad.

**NOTE**

*It may be necessary to compensate for residual noise effects using the procedure presented in the manual provided with the Modulation Analyzer.*

5. Repeat step 3 at frequencies of 320, 160, 80, 40, 20, and 14 MHz.
6. Insert the microwave converter between the UUT RF OUTPUT and the modulation meter RF input.
7. Repeat steps 3 and 4 at 1300, 1600, 1900, and 2112 MHz.

**Frequency Modulation Tests**

**3-19.**

**REMARKS:**

If the UUT fails these performance tests, calibrate and/or repair the associated circuitry.

The UUT settings in this procedure are chosen to provide strong confidence in the modulation performance of the UUT throughout its range. If desired, however, performance may also be checked at other instrument settings.

**TEST EQUIPMENT:**

- Modulation analyzer
- Microwave converter
- Distortion analyzer
- High-frequency synthesized Signal Generator (HFSSG)

**REQUIREMENTS:**

FM Accuracy:  $\pm(5\%$  of setting +10Hz) for rates from 50 Hz to 50 kHz.

**FM Distortion:**

Standard Mode:  $<2\%$  for 0.5 to 1.0 times maximum deviation;  $<1\%$  for  $<0.5$  times maximum deviation. Applies for rates of 50 Hz to 50 kHz.

Low Distortion Mode:  $<0.30\%$  for peak deviation  $\leq 3.5$  kHz, and rates 0.3 to 3 kHz.

FM 3-dB Bandwidth: as listed in Table 3-8.

**Table 3-8. FM 3-dB Bandwidth**

DEVIATION	COUPLING	
	INTERNAL AC	EXTERNAL AC (DC)
0% to 25% Maximum	20 Hz to 175 kHz	20 Hz to 175 kHz
25% to 100% Maximum	20 Hz to 100 kHz	20 Hz (ac) to 100 kHz

Incidental AM:  $<1\%$  depth for deviation  $<100$  kHz at 1 kHz rate and carrier frequency  $>0.5$  MHz.

**PROCEDURE (FM Accuracy and Distortion Test):**

1. Connect the modulation analyzer directly to the UUT RF OUTPUT.
2. Program the modulation analyzer to measure peak FM in a 0.3- to 3-kHz bandwidth.
3. Program the UUT frequency to 640 MHz, +7 dBm, 20-kHz deviation, INT FM and 1-kHz modulation rate.

## PERFORMANCE TESTS

4. Set the distortion analyzer to measure distortion at 1 kHz.
5. Verify that the modulation analyzer reading is between 19 and 21 kHz, and that the THD is less than 1%. Repeat at deviations of 5 and 10 kHz. Verify that the modulation analyzer reading is within  $\pm 5\%$  of the programmed value.
6. Program the UUT to a deviation of 50, 100, and 200 kHz.
7. Verify that the modulation analyzer reading and distortion passes the test requirements.

### NOTE

*Change the modulation analyzer bandwidth and distortion analyzer frequency appropriately for modulation frequency for steps 8 through 16.*

8. Repeat steps 4 through 7 with the modulation rate set to 100 Hz. Verify distortion only.
9. Repeat steps 4 through 7 with the modulation rate set to 50 kHz. Verify distortion only.
10. Program UUT to 40-MHz frequency, 25-kHz deviation, and 1-kHz INT modulation frequency.
11. Verify that the modulation analyzer reading and distortion is per the requirements.
12. Program the UUT to deviations of 50, 100, 200, and 250 kHz.
13. Verify that the modulation analyzer readings and distortion is per the requirements.
14. Repeat steps 10 through 13 with the modulation rate set to 100 Hz. Verify distortion only.
15. Repeat steps 10 through 13 with the modulation rate set to 50 kHz. Verify distortion only.

### NOTE

*It may be necessary to compensate for residual noise effects using the procedure presented in the manual provided with the modulation analyzer.*

#### PROCEDURE (Incidental AM Test):

1. Program the UUT for 100-kHz deviation, INT FM on at 1 kHz, EXT FM off, a level of +7 dBm, and a frequency of 14 MHz.
2. Program the modulation analyzer to measure peak AM in a 0.3- to 3-kHz bandwidth.
3. Verify that the incidental AM is less than 1%.

4. Repeat steps 1 through 3 at frequencies of 20, 30, 40, 60, 80, 100, 160, 250, 320, 400, 550, 640, 700, 850, 950, and 1056 MHz.
5. Insert the microwave converter between the UUT RF OUTPUT and the modulation meter RF input.
6. Program the UUT to 1100 MHz, +7 dBm, INT FM, 100 kHz deviation, and 1 kHz modulation frequency.
7. Repeat steps 2 and 3.
8. Repeat steps 2 and 3 at 1300, 1600, 1900, and 2112 MHz.

**PROCEDURE (FM Bandwidth Test):**

1. Program the UUT to 14 MHz, +7 dBm, 1 kHz Mod Rate, INT FM, and 25% of Max Dev (125 kHz at 14 MHz).
2. Connect the UUT RF OUTPUT directly to the modulation meter RF input.
3. Set the modulation analyzer low low-pass filtering to all-off, read FM Peak+, and press the Ratio DB key. (Normalize reading to 0.00 dB.)
4. Set the UUT modulation frequency to 175 kHz. Verify the modulation meter reading is above -3 dB.
5. Repeat steps 1 through 3 for the following frequencies: 20, 40, 100, 200, 300, 750, and 1300 MHz.
6. Repeat steps 1 through 5 with the FM deviation set at the maximum for each frequency and the modulation rate set for 100 kHz.

**Phase Modulation Tests**

**3-20.**

**REMARKS:**

If the UUT fails these performance tests, calibrate and/or repair the associated circuitry.

The UUT settings in this procedure are chosen to provide strong confidence in the modulation performance of the UUT throughout its range; however, you can also check the performance at other Signal Generator settings.

**TEST EQUIPMENT:**

- Modulation analyzer
- Microwave converter
- Distortion analyzer
- High-frequency synthesized Signal Generator (HFSSG)

**REQUIREMENTS:**

Phase Modulation Accuracy:  $\pm(5\%$  of setting + 0.1 radian) at 1-kHz rate.

## PERFORMANCE TESTS

Phase Modulation Distortion:  $<2\%$  for 0.5 to 1.0 times maximum deviation;  $<1\%$  for  $<0.5$  times maximum deviation. Applies for 1-kHz rate in standard mode, and from 50 Hz to 50 kHz in high rate mode.

Phase Modulation 3-dB External Bandwidth: Standard Mode: 20 Hz to 15 kHz, ac coupled; dc to 15 kHz, dc coupled. High rate mode: 20 Hz to 100 kHz, ac coupled; dc to 100 kHz, dc coupled.

Incidental AM:  $<1\%$  depth for peak deviation  $<10$  radians at 1-kHz rate and carrier frequency  $>0.5$  MHz.

### PROCEDURE ( $\phi$ M Accuracy and Distortion Test):

1. Connect the modulation analyzer directly to the UUT RF OUTPUT.
2. Program the modulation analyzer to measure peak  $\phi$ M in a 0.3- to 3-kHz bandwidth.
3. Program the UUT frequency to 640 MHz, +7 dBm, 20 radians, INT  $\phi$ M and 1-kHz modulation rate.
4. Set the distortion analyzer to measure distortion at 1 kHz.
5. Verify that the modulation analyzer reading is between 19 and 21 radians, and that the THD is less than 1%. Repeat at deviations of 5 and 10 radians. Verify that the modulation analyzer reading is within  $\pm 5\%$  of programmed value. (See the following NOTE.)

### NOTE

*For steps 8 through 15, change the modulation analyzer bandwidth and distortion analyzer frequency appropriately for modulation frequency.*

6. Program the UUT to deviations of 50, 100, and 200 radians.
7. Verify that the modulation analyzer reading and distortion is per the requirements.
8. Repeat steps 4 through 7 with the modulation rate set to 100 Hz. Verify distortion only.
9. Program the UUT to 40-MHz frequency, 2.5 radians deviation and 1-kHz INT modulation frequency.
10. Verify that the modulation analyzer reading is between 2.375 and 2.625 and that the distortion is less than 5%.
11. Program the UUT to deviation of 5, 10, 20, and 25 radians.
12. Verify that the modulation analyzer readings and the distortion is per the requirements.
13. Repeat steps 9 through 12 with the modulation rate set to 100 Hz. Verify distortion only.

**NOTE**

*It may be necessary to compensate for residual noise effects using the procedure presented in the manual provided with the modulation analyzer.*

**PROCEDURE (Incidental AM Test):**

1. Program the UUT for 100-kHz deviation, INT FM on at 1 kHz, EXT FM off, a level of +7 dBm, and a frequency of 14 MHz.
2. Program the modulation analyzer to measure peak AM in a 0.3- to 3-kHz bandwidth.
3. Verify that the incidental AM is less than 1%.

**REQUIREMENTS:**

Phase Modulation Accuracy:  $\pm(5\%$  of setting + 0.1 radian) at 1-kHz rate.

Phase Modulation Distortion:  $<2\%$  for 0.5 to 1.0 times maximum deviation;  $<1\%$  for  $<0.5$  times maximum deviation. Applies for 1-kHz rate in standard mode, and from 50 Hz to 50 kHz in high rate mode.

Phase Modulation 3-dB External Bandwidth: Standard Mode: 20 Hz to 15 kHz, ac coupled; dc to 15 kHz, dc coupled. High rate mode: 20 Hz to 100 kHz, ac coupled; dc to 100 kHz, dc coupled.

Incidental AM:  $<1\%$  depth for peak deviation  $<10$  radians at 1-kHz rate and carrier frequency  $>0.5$  MHz.

**PROCEDURE ( $\phi$ M Accuracy and Distortion Test):**

1. Connect the modulation analyzer directly to the UUT RF OUTPUT.
2. Program the modulation analyzer to measure peak  $\phi$ M in a 0.3- to 3-kHz bandwidth.
3. Program the UUT frequency to 640 MHz, +7 dBm, 20 radians, INT  $\phi$ M and 1-kHz modulation rate.
4. Set the distortion analyzer to measure distortion at 1 kHz.
5. Verify that the modulation analyzer reading is between 19 and 21 radians, and that the THD is less than 1%. Repeat at deviations of 5 and 10 radians. Verify that the modulation analyzer reading is within  $\pm 5\%$  of programmed value. (See the following NOTE.)

**NOTE**

*For steps 8 through 15, change the modulation analyzer bandwidth and distortion analyzer frequency appropriately for modulation frequency.*

## PERFORMANCE TESTS

6. Program the UUT to deviations of 50, 100, and 200 radians.
7. Verify that the modulation analyzer reading and distortion is per the requirements.
8. Repeat steps 4 through 7 with the modulation rate set to 100 Hz. Verify distortion only.
9. Program the UUT to 40-MHz frequency, 2.5 radians deviation and 1-kHz INT modulation frequency.
10. Verify that the modulation analyzer reading is between 2.375 and 2.625 and that the distortion is less than 5%.
11. Program the UUT to deviation of 5, 10, 20, and 25 radians.
12. Verify that the modulation analyzer readings and the distortion is per the requirements.
13. Repeat steps 9 through 12 with the modulation rate set to 100 Hz. Verify distortion only.

### NOTE

*It may be necessary to compensate for residual noise effects using the procedure presented in the manual provided with the modulation analyzer.*

### PROCEDURE (Incidental AM Test):

1. Program the UUT for 10 radians deviation, INT  $\phi$ M on, 1 kHz mod rate, EXT  $\phi$ M off, a level of +7 dBm, and a frequency of 14 MHz.
2. Program the modulation analyzer to measure peak AM in a 0.3- to 3-kHz bandwidth.
3. Verify that the incidental AM is less than 1%.
4. Repeat steps 1 through 3 at frequencies of 20, 30, 40, 60, 80, 100, 160, 250, 320, 400, 550, 640, 700, 850, 950, and 1056 MHz.
5. Insert the microwave converter between the UUT RF OUTPUT and the modulation meter RF input.
6. Program the UUT to 1100 MHz, +7 dBm, INT  $\phi$ M, 10 radians deviation, and 1 kHz modulation rate.
7. Repeat steps 2 and 3.
8. Repeat steps 2 and 3 at 1300, 1600, 1900, and 2112 MHz.

**PROCEDURE ( $\phi$ M Bandwidth Test):**

1. Program the UUT to: 14 MHz, +7 dBm, 1 kHz mod rate, INT  $\phi$ M, and 25% of maximum deviation (12.5 radians at 14 MHz).
2. Connect the UUT RF OUTPUT directly to the modulation meter RF input.
3. Set the modulation analyzer low-pass filtering to all-off, read  $\phi$ M Peak+, and press the Ratio  $\phi$ M key. (Normalize reading to 0.00 dB.)
4. Set the UUT modulation frequency to 15 kHz. Verify that the modulation meter reading is above -3 dB.
5. Repeat steps 1 through 3 for frequencies: 20, 40, 100, 200, 300, 750, and 1300 MHz.

**VOLTAGE STANDING-WAVE RATIO (VSWR) TESTS****3-21.**

The Voltage Standing-Wave ratio (VSWR) tests use a VSWR bridge and a spectrum analyzer to verify VSWR of the UUT.

**REQUIREMENTS:**

The output VSWR is less than 1.5:1 for output levels < +6 dBm; < 2.0:1 for levels above +6 dBm.

**TEST EQUIPMENT:**

- VSWR bridge
- RF spectrum analyzer
- High-frequency synthesized Signal Generator (HFSSG)

**REMARKS:**

The UUT settings in this procedure are chosen to provide confidence in the VSWR performance of the UUT throughout its range; however, you can also check the performance at other levels.

VSWR problems are most likely to involve the A31 Output PCA or the A34 Attenuator PCA.

**NOTE**

*Perform the following procedures in the order in which they are presented to ensure that the proper equipment is connected and appropriate programs are enabled.*

**PROCEDURE (Low-Level Test):**

1. Turn on the UUT and program it to RCL 98.
2. Program the UUT to 640 MHz at +6 dBm.

## PERFORMANCE TESTS

3. Press **SPCL** **5** **1** to select the fixed range special function on the UUT.
4. Use the EDIT function on the UUT to edit the amplitude to -30 dBm. Verify that the UNCAL annunciator lights.

### NOTE

*This procedure leaves the output attenuators set as they would be for a +6 dBm output level but uses the electronic control to turn down the RF level coming out of the UUT.*

5. Connect the UUT to the Device Under Test port of the VSWR bridge.
6. Connect the RF spectrum analyzer to the RF OUT port of the VSWR bridge.
7. Connect the HFSSG to the RF IN port of the VSWR bridge.
8. Program the HFSSG to 10 MHz at +13 dBm.
9. Set the RF spectrum analyzer to display approximately 10 to 2112 MHz and set the reference level to +10 dBm.
10. Step the HFSSG from 10 to 2112 MHz in 10-MHz steps. Locate the frequency at which the reflected signal (displayed by the RF spectrum analyzer) is maximum and record this level. This is the point with the worst-case VSWR.
11. Disconnect the UUT from the VSWR bridge and record the new level.
12. Calculate the return loss (difference) between the two recorded levels. The difference must be at least 14 dB (14 dB of return loss = 1.5:1 VSWR).

### PROCEDURE (High-Level Test):

1. Program the UUT to +10 dBm.
2. Press **SPCL** **5** **1** to select the special function fixed range on the UUT.
3. Use the EDIT function on the UUT to edit the amplitude to -30 dBm.
4. Connect the UUT to the Device Under Test port of the VSWR bridge.
5. Step the HFSSG from 10 to 2112 MHz in 10-MHz steps. Locate the frequency at which the reflected signal is maximum and record this level.
6. Disconnect the UUT from the VSWR bridge and record the new level.
7. Calculate the return loss between the two recorded levels. The difference must be at least 9.5 dB (9.5 dB of return loss = 2.0:1 VSWR).

**PULSE TESTS****3-22.**

The Pulse Tests check the static and dynamic operation of pulse modulation.

**REQUIREMENTS:**

Proper pulse operation is tested by checking the following:

On/Off Ratio: 80 dB

Rise/Fall time: <15 ns, 10% to 90%. Typically 7.5 ns. Output Level Accuracy: Within  $\pm 0.7$  dB of CW accuracy for pulse widths >50 ns.

**TEST EQUIPMENT:**

- RF spectrum analyzer
- Pulse generator
- Power meter
- Power sensor (high level)
- 50 $\Omega$  termination
- Oscilloscope
- Detector

**NOTE**

*The following procedures must be performed in the order given to ensure that the proper equipment is connected and the appropriate programs are enabled.*

**PROCEDURE (Static Test):**

1. Program the UUT to 100 kHz and +10 dBm.
2. Connect a 50 $\Omega$  termination to the pulse modulation input connector.
3. Connect the UUT RF OUTPUT to the RF spectrum analyzer input.
4. Set the RF spectrum analyzer controls to display the output of the UUT using a span of approximately 0.1 MHz.
5. Activate pulse modulation by pressing the External Pulse key on the UUT.
6. Observe the level change on the RF spectrum analyzer. The change should exceed 80 dB.
7. Deactivate external pulse by pressing **EXP** on the UUT, and repeat steps 4 through 6 for UUT frequencies of 1, 14.9, 15, 50, 100, 500, 1000, 1300, 1600, 1900, and 2112 MHz.

**PROCEDURE (Dynamic Test):**

1. Program the UUT to 640 MHz, +10 dBm, and external pulse modulation.

## PERFORMANCE TESTS

2. Connect the pulse generator to the UUT pulse input connector.
3. Set the pulse generator to a repetition rate of 5 MHz, +3V pulse level, and roughly a 50% duty cycle.
4. Connect the output of the UUT to the detector.
5. Terminate the detector into 50 $\Omega$  at the oscilloscope input.
6. Set the time base of the oscilloscope to 10 nanoseconds (or smaller) per division.
7. Use the oscilloscope channel to invert the detector output signal.
8. Trigger the oscilloscope on this signal.
9. Set the variable position and gain on the oscilloscope so that the signal extends from 0% to 100% on the graticule.
10. Measure the rise/fall time from the 90% to the 10% coordinates.
11. Verify that the rise/fall time is < 15 nanoseconds.

### PROCEDURE (Level Error Test):

1. Remove the UUT, and reconnect the pulse generator directly into the oscilloscope.
2. Set the pulse generator to 5-MHz repetition rate, +3V level, and 50% duty cycle.
3. Adjust the oscilloscope position and gain controls for easy full-scale viewing.
4. Readjust the pulse duty cycle for exactly 50% as measured at the 1V level of the oscilloscope.
5. Remove the pulse generator from the oscilloscope, and reconnect it to the pulse input of the UUT.
6. Program the UUT to 100 MHz, +7dBm, and external pulse modulation.
7. Connect the UUT output to the RF spectrum analyzer input.
8. Set the RF spectrum analyzer to observe a three-line spectra on either side of the center line spectra. The center spectra may be verified by turning pulse modulation off. (Use a spectrum analyzer setting of 5 MHz/div span and 100 kHz resolution bandwidth.)
9. Adjust the duty cycle of the pulse generator for exactly 50% duty cycle by nulling the second line from the center line (approximately 10-MHz offset). Establish a null of -30 dBc or below.
10. Replace the RF spectrum analyzer with the power meter, and set the power meter to the reference setting.

11. Turn the UUT pulse modulation off and note the meter reading. The difference between the meter reading and 3.01 dB is the pulse level error. This error should be less than 0.7 dB.
12. Repeat steps 6 through 11 for 500, 1056, 1500, and 2112 MHz.

**INTERMODULATION TEST**

**3-23.**

**REQUIREMENTS:**

Third-Order Intermodulation: Applies with each signal level at +4 dBm into a resistive combiner. Refer to Table 3-9 for this test.

Table 3-9. Intermodulation Requirements

APPROXIMATE CARRIER FREQUENCY BAND (MHz)	SIGNAL SPACING	
	1 kHz	25 kHz
512 to 2112	-65 dBc	-70 dBc
128 to 512	-65 dBc	-75 dBc
0.1 to 128	-60 dBc	-75 dBc

**TEST EQUIPMENT:**

- RF spectrum analyzer (Intermod)
- 3-dB hybrid
- High-frequency synthesized Signal Generator (HFSSG)
- 6-dB resistive combiner

**REMARKS:**

The first part of this test is necessary to verify that the spectrum analyzer has a low enough level of internally generated intermodulation distortion (IMD) to allow the UUT measurement to be valid.

**Equipment Verification**

**3-23.**

**PROCEDURE:**

1. Connect the UUT and the HFSSG to the spectrum analyzer through isolated ports of the 3-dB hybrid.
2. Connect the spectrum analyzer 10-MHz output to the UUT and HFSSG 10 MHz inputs and set the UUT and HFSSG to EXT REF.
3. Program the UUT to RCL 98, 50 MHz, and +4 dB.
4. Program the HFSSG to RCL 98, 50.025 MHz, and +4 dBm.

## PERFORMANCE TESTS

5. Set the starting spectrum analyzer settings as follows:
  - a. RF attenuation 20 dB
  - b. Reference level 0 dBm
  - c. Center frequency 49.975 MHz
  - d. Frequency span 100 kHz
6. Adjust the reference level to place the UUT signal at the top graticule of the display.
7. Place a marker on the IMD product at 49.975 MHz.
8. Increase the spectrum analyzer RF attenuation to 30 and then to 40 dB while observing the IMD product at the marker. It will be necessary to reduce the frequency span to 1 kHz or less and reduce both the resolution bandwidth and video bandwidth to 10 Hz.
9. The IMD product at 49.975 MHz should be 85 dB or more below the UUT carrier level.
10. Repeat steps 3 through 9 at 500 and 1500 MHz. Measurement values should be -85, -80, and -80 dBc or below, respectively. If these values (from steps 9 and 10) cannot be realized, the measurements on the UUT will likely be invalid.

### Intermodulation Distortion Test

3-24.

1. Connect the UUT and the HFSSG to the spectrum analyzer through the 6 dB resistive combiner.
2. Connect the spectrum analyzer 10 MHz out to the UUT and HFSSG 10-MHz inputs and set the UUT and HFSSG to EXT REF.
3. Program the UUT to RCL 98, 50 MHz, and +4 dBm.
4. Program the HFSSG to RCL 98, 50.025 MHz, and +4 dBm.
5. Set the starting spectrum analyzer settings as follows:
  - a. RF attenuation 20 dB.
  - b. Reference level 0 dBm.
  - c. Center frequency 49.975 MHz.
  - d. Frequency span 100 kHz.
6. Adjust the reference level to place the UUT signal at the top graticule of the display.
7. Place a marker on the IMD product at 49.975 MHz.

8. Change the spectrum analyzer settings as follows:
  - a. Frequency span 1 kHz.
  - b. Resolution bandwidth 10 Hz.
  - c. Video bandwidth 10 Hz.
9. The IMD product should be -75 dBc or below, as stated in the requirements.
10. Repeat steps 3 through 9 at 500, 1000, and 1500 MHz. The measurements should be -75, -70, and -70 dBc or below, respectively.

## Section 4

# Closed-Case Calibration

### INTRODUCTION

4-1.

The procedures in this section calibrate the RF output level, AM depth, FM deviation, and the internal 10-MHz reference oscillator without requiring that the instrument covers be removed. You can perform the procedures directly by pressing the front panel keys, or remotely under the control of an IEEE-488 bus controller.

Perform the calibration procedures at the specified two-year calibration intervals or as needed to optimize 6082A Synthesized RF Signal Generator performance.

Each procedure includes the following steps:

1. Set the rear panel CAL|COMP switch to the 1 (on) position.
2. Initiate the calibration procedure.
3. Connect the required measurement equipment to the signal generator's RF OUTPUT.
4. Adjust the parameter of interest until the meter reading matches a predetermined target value.
5. Store the updated calibration factor.

These calibration procedures cannot correct hardware failures. If calibration fails to adjust the signal generator to proper specifications, consult Section 6, Circuit Descriptions, Troubleshooting, and Alignment for troubleshooting and repair information.

### Front Panel Calibration

4-2.

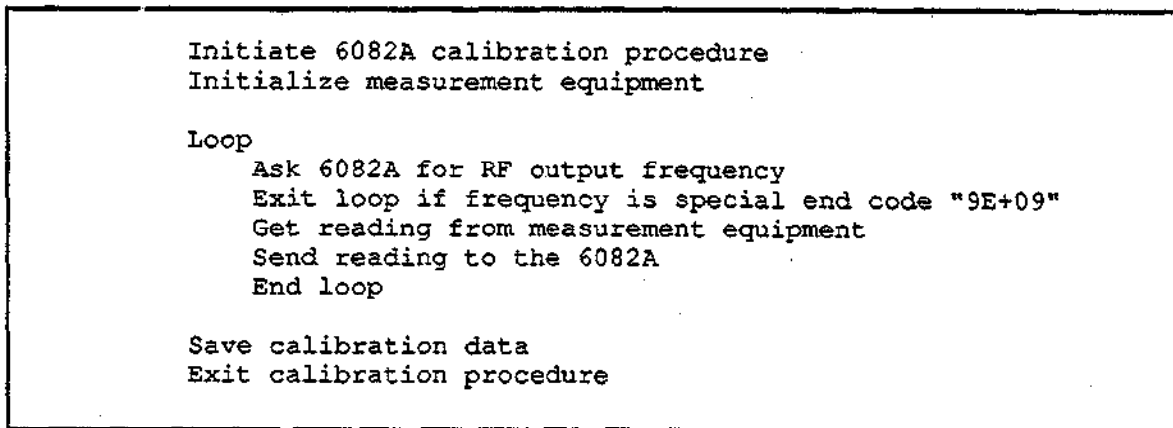

The front panel calibration procedures describe the steps required to perform each test. The edit knob increases or decreases the bright-digit value. You must adjust the bright-digit value until the 6082A reading matches the target value.

**Remote Calibration**

4-3.

Remote calibration procedures allow the signal generator to be automatically calibrated by an IEEE bus controller. When connected to the required measurement equipment and under control of appropriate bus controller software, calibration consists of simply connecting cables to the instruments and executing the program.

The basic structure of a calibration program is shown in Figure 4-1.

**Figure 4-1. Basic Structure of Calibration Program**

A remote calibration procedure begins when the bus controller initializes the measurement equipment by initiating the firmware calibration program located in the signal generator. The controller then requests the signal generator's RF output frequency and waits for a response. The controller requests the RF output frequency each time through the main loop to synchronize the controller with the signal generator and to provide an exit point when the procedure is complete.

When the bus controller receives the response from the signal generator, it gets a reading from the measurement equipment, ensures the reading is settled and valid, and converts the reading into a format understood by the signal generator. The controller then sends the reading to the signal generator, which uses the reading to update its internal settings. The signal generator does not respond to the next frequency query until it is ready for another reading. The controller waits for the signal generator's output to settle before taking another measurement reading.

The signal generator continues to receive readings and make internal adjustments until it gets two consecutive readings within the error tolerance for the procedure. The error tolerance is defined for each procedure as a range of readings around the target value that the signal generator expects to receive when the adjustment is correct. When two readings are within the error tolerance, the adjustment is considered valid.

The program remains in the main loop until the signal generator returns the end code "9E+09, HZ", in response to the next frequency query. When the controller receives the end code, it exits the loop and saves the measurement data in the signal generator's calibration memory.

The division of responsibility between the controller and signal generator allows the use of measurement equipment from various manufacturers. Adding a different meter to the system requires only that a new driver module be written for the controller.

#### NOTE

*The accuracy of the remote calibration procedure depends largely on the design of the controller software. Before sending the result to the 6082A, determine that the readings are settled, and average several readings. Where applicable, apply meter-specific calibration factors to the readings.*

Sample controller programs for each remote procedure are included in Appendix G. The programs are written in Fluke BASIC and are provided as examples of the programs that will run on a Fluke 1722A controller.

### Calibration Data

4-4.

After making internal adjustments, the signal generator stores calibration data along with compensation data in non-volatile memory. Two copies of data provide a redundant storage scheme to enhance data integrity. The two copies are stored in separate locations: one copy is stored in the battery-backed RAM and an identical copy is stored in the EEPROM.

Calibration data are generated either by the Fluke factory or by the user. Each calibration data segment contains a data origin code that specifies how the data segment was created.

The calibration and compensation data origin codes display when special function 05 is entered. Origin code 00 signifies that the data originated at the Fluke factory; therefore, no user calibration or compensation procedures have been performed. If any user calibration procedures have been performed, the corresponding code is displayed. For example, if the AM calibration procedure has been performed by the user, the data origin special function displays the code 528. A complete list of the data origin codes is given in Appendix F.

Refer to the Operator Manual for more information about special functions.

### CALIBRATION SETUP

4-5.

Before beginning the procedures, set the rear panel slide switch labeled CAL|COMP to the 1 (on) position. Setting the rear panel switch to this position causes the CAL and COMP annunciators to blink, indicating that a calibration procedure can be selected when  is pressed. When a calibration procedure is initiated, the CAL and COMP annunciators stop blinking and the CAL annunciator remains lit until the procedure is complete. When the rear panel switch is in the 0 (off) position, the data is write-protected in hardware.

### AM CALIBRATION

4-6.

The AM calibration procedures allow a single point calibration of the am depth. An RF modulation meter is connected to the 6082A's RF output and the AM calibration factor is adjusted based on the meter reading. The parameters specific to this procedure are listed below:

- Adjustment Range:  $\pm 5\%$  AM Depth
- Adjustment Resolution: 0.1%
- Target Value: 50.0%
- RF Frequency: 300.000000 MHz
- RF Level: +10.0 dBm
- Internal AM: ON
- Modulation Frequency: 1 kHz
- External Equipment: RF Modulation Analyzer (HP 8901A or equivalent)

When performing the front panel procedure, use the edit knob to adjust the AM depth until the measured AM depth matches the target value. During the remote calibration procedure, a program running on an IEEE-488 bus controller directs the procedure.

Both the front panel and remote calibration procedures reconfigure the front panel display in the following ways: the target level displays in the modulation field, the RF frequency displays in the frequency field, the adjustment value displays in the amplitude field, and the CAL annunciator lights.

All adjustments update a temporary copy of the AM calibration factor. The copy in the calibration memory updates only after the store command is given explicitly. After the store command has been given, the internal calibration factor is calculated from the displayed adjustment value and is stored in the calibration memory. Subsequent AM programming commands use the new calibration factor.

### Front Panel AM Calibration Procedure

4-7.

This procedure disables several of the front panel controls or causes them to operate differently than they normally do. It also reconfigures the display.

Table 4-1 lists the front panel controls used in the calibration procedures and describes the function of each.

Proceed as follows to perform the front panel AM calibration procedure:

1. Set the rear panel CAL|COMP switch to 1 (on) position.
2. Enter special function 991 to initiate the AM calibration procedure.
3. Connect the RF OUTPUT of the 6082A to the modulation meter.
4. Select the peak+ mode, enable the 50-Hz high-pass filter, and enable the 3 kHz low-pass filter on the modulation meter.
5. Use the edit knob to change the adjustment value until the modulation meter reads 50.0%.
6. Press  twice to store the new data.

### Remote AM Calibration Procedure

4-8.

The following paragraphs describe the remote AM calibration procedure, the remote commands needed for this procedure, and the elements required to build a functioning controller program. Refer to the Remote Calibration, earlier in this section, for general information about remote calibration.

Table 4-1. Front Panel Controls Function for Calibration Procedures

CONTROLS	FUNCTION AND DESCRIPTION
 	Bright-Digit Editing
KNOB	Turn the edit knob to change the adjustment value. Use the left/right arrow keys to move the bright-digit within the adjustment field. The bright-digit is always located in the adjustment field.
	RF on/off Toggles the RF output on/off.
	Overrange/uncal or Rejected Entry Status Normally displays the overrange/uncal status. Displays the rejected entry status code if there is a rejected entry.
	Store Measured Data Press once; the prompt "Sto ?" is displayed. Press again to store the data. The message "-- Sto --" is displayed to confirm the selection. The updated calibration factor is stored in the calibration memory, and the last valid instrument state is restored. Press any other key to cancel the store operation and resume the procedure.
	Abort the Cal Procedure Press once; the prompt "Clr ?" is displayed. Press again to abort the procedure. The message "-- Clr --" is displayed to confirm the selection. All measured data is discarded and the previous instrument state is restored. Press any other key to resume the procedure.

A sample controller program for the remote AM calibration procedure is contained in Appendix G. The program is written in Fluke BASIC and is provided as an example of the programs that will run on a Fluke 1722A controller.

Table 4-2 provides information needed to create a remote calibration program. This table lists specific commands that must be included in the AM calibration program. Table 5B-3 in Section 5B of the Operator Manual describes the syntax of each command.

Figure 4-2 outlines the operation of the program in this procedure.

Table 4-2. Remote Programming Commands for AM Calibration Procedure

COMMANDS	DESCRIPTION
CAL_AM	Initiate the remote AM calibration procedure
CC_RDAM	Send the mod meter reading to the 6082A
CC_FREQ?	Request the RF frequency
CC_TARGET?	Request the target value
RFOUT	Program the RF output on/off
CC_SAVE	Save the measured data
CC_EXIT	Abort the cal procedure immediately
ERROR?	Request the rejected entry status
STATUS/STATUS?	Load/Request the overrange/uncal status

```
Initiate the AM calibration procedure with "CAL_AM"  
Initialize modulation meter  
  
MAIN_LOOP:  
  Request the RF frequency with "CC_FREQ?"  
  
  If( frequency = 9e9) goto DONE  
  
  Read modulation meter  
  Send reading to 6082A with "CC_RDAM"  
  
  Goto MAIN_LOOP  
  
DONE:  
  Store new data in calibration memory with "CC_SAVE"  
  End
```

Figure 4-2. Structure of the AM Calibration Program

Proceed as follows to initiate the remote AM calibration procedure:

1. Set the rear panel CAL|COMP switch to 1 (on) position.
2. Initiate the bus controller program.

During the operation of the remote calibration procedure, the controller requests the signal generator's center frequency with the command CC\_FREQ? and waits for a response.

When a response is received, the controller gets a modulation meter reading. The controller program ensures that each modulation meter reading is settled before sending the reading to the signal generator with the command CC\_RDAM.

The signal generator receives the reading, adjusts its internal settings, and programs the new AM depth. The program continues to loop until the signal generator receives two consecutive readings within an error tolerance of 0.1%. At that point it considers the adjustment value correct and returns the end code "9E+09, HZ" to the controller in response to the CC\_FREQ? command.

The program exits the main loop and saves the data by sending out the CC\_SAVE command.

## FM CALIBRATION

4-9.

The FM calibration procedure allows a single point calibration (see listing below) of the FM deviation. The adjustment of the FM calibration factor is based on the reading of an RF modulation meter connected to the 6082A's RF output. The specific parameters for this procedure are listed below:

- Adjustment Range:  $\pm 10$  kHz
- Adjustment Resolution: 0.1 kHz

- Target Value: 100 kHz
- Frequency: 640.000000 MHz
- RF Level: +10.0 dBm
- Internal FM: ON
- Modulation Frequency: 1 kHz
- External Equipment: RF Modulation Analyzer (HP 8901A or equivalent)

To perform the front panel procedure, use the edit knob to adjust the FM deviation until the measured deviation matches the target value. During the remote calibration procedure, a program running on an IEEE-488 bus controller directs the procedure.

Both the front panel and remote calibration procedures reconfigure the front panel display in the following ways: the target level displays in the modulation field, the RF frequency displays in the frequency field, the adjustment value displays in the amplitude field, and the CAL annunciator lights.

All adjustments update a temporary copy of the FM calibration factor. The copy in the calibration memory is updated only after the store command is given explicitly. After the store command has been given, the internal calibration factor is calculated from the displayed adjustment value and is stored in the calibration memory. Subsequent FM programming commands use the new calibration factor.

### Front Panel FM Calibration Procedure

4-10.

The display is reconfigured for the front panel FM calibration procedure. Several of the front panel controls are disabled or operate differently than they normally do. Table 4-1 lists the active front panel controls and describes their function during the calibration procedure.

Proceed with the following steps to execute the front panel FM calibration procedure:

1. Set the rear panel CAL|COMP switch to the 1 (on) position.
2. Enter special function 992 to initiate the FM procedure.
3. Connect the 6082A's RF OUTPUT to the modulation meter.
4. Select the peak+ mode, enable the 50 Hz high-pass filter, and enable the 3 kHz low-pass filter on the modulation meter.
5. Use the edit knob to change the adjustment value until the modulation meter reads 100 kHz.
6. Press the sto key twice to store the new data.

### Remote FM Calibration

4-11.

The following paragraphs describe the remote FM calibration procedure, the remote commands needed for this procedure, and the elements required to build a functioning controller program. Refer to the Remote Calibration, earlier in this section, for general information about remote calibration.

A sample controller program for the remote FM calibration procedure is contained in Appendix G. The program is written in Fluke BASIC and is provided as an example of the programs that will run on a Fluke 1722A controller.

Table 4-3 provides information needed to create a remote calibration program. This table lists specific commands that must be included in the FM calibration program. Table 5B-3 in Section 5B of the Operator Manual describes the syntax of each command.

Table 4-3. Remote Programming Commands for FM Calibration Procedure

COMMANDS	DESCRIPTION
CAL_LEVEL	Initiate the remote level calibration procedure
CC_RDPOWER	Send the power meter reading to the 6082A
CC_FREQ?	Request the RF frequency
CC_TARGET?	Request the target value
RFOUT	Program the RF output on/off
CC_SAVE	Save the measured data
CC_EXIT	Abort the cal procedure immediately
ERROR?	Request the rejected entry status
STATUS/STATUS?	Load/Request the overrange/uncal status

Figure 4-3 outlines the operation of the program in this procedure.

```

Initiate the FM calibration procedure with "CAL_FM"
Initialize modulation meter

Main Loop
  Request the RF frequency with "CC_FREQ?"

  If( frequency = 9e9) goto DONE

  Read modulation meter
  Send reading to 6082A with "CC_RDFM"

  Goto Main Loop

DONE
Store new data in calibration memory with "CC_SAVE"
End
    
```

Figure 4-3. Structure of the FM Calibration Program

Proceed as follows to initiate the remote FM calibration procedure:

1. Set the rear panel CAL|COMP switch to I (on) position.
2. Initiate the bus controller program.

The bus controller initiates the procedure with the CAL\_FM command. The controller requests the signal generator's center frequency with the CC\_FREQ? command and waits for a response.

When a response is received, the controller gets a mod meter reading. The controller program ensures that each meter reading is settled before sending the reading to the signal generator with the command CC\_RDFM.

Each time the signal generator receives a reading from the controller, it adjusts its internal settings and programs the new FM deviation.

The program remains in the main loop until the signal generator receives two consecutive readings within 0.1 kHz of the target value (100 kHz). At this time it considers the displayed adjustment value correct and returns the end code "9E+09, HZ" in response to the CC\_FREQ? command.

The program exits the main loop and saves the data by sending out the CC\_SAVE command.

## RF LEVEL CALIBRATION

4-12.

The RF level calibration procedures perform a single-point calibration of the RF output level. An RF power meter is connected to the signal generator's RF OUTPUT and the level calibration factor is adjusted based on the meter reading. The parameters specific to this procedure are as follows:

- Adjustment Range:  $\pm 1.00$  dB
- Adjustment Resolution: 0.01 dB
- Target Value: 10.0 dBm
- Frequency: 300.000000 MHz
- RF Level: +10.0 dBm
- External Equipment: RF Power Meter (HP 436A or equivalent)

When performing the front panel procedure, use the edit knob to adjust the level until the measured level matches the target level. The remote calibration procedure is controlled by a program running on an IEEE-488 bus controller.

Both the front panel and remote calibration procedures reconfigure the front panel display in the following ways: the target level displays in the modulation field, the RF frequency displays in the frequency field, the adjustment value displays in the amplitude field, and the CAL annunciator lights.

All adjustments update a temporary copy of the adjustment value. The copy in the calibration memory is updated only after the store command is given explicitly by the user or remote controller. After the store command is received by the signal generator, the internal calibration factor is calculated from the displayed adjustment value and is stored in the calibration memory. Subsequent amplitude programming commands use the new calibration factor.

### Front Panel Level Calibration Procedure

4-13.

The display is reconfigured for the procedure. Several of the front panel controls are disabled or operate differently than they normally do.

Table 4-1 lists the active front panel controls and describes the function of each.

Proceed as follows to execute the front panel level calibration procedure:

1. Set the rear panel CAL|COMP switch to the 1 (on) position.
2. Enter special function 993 to initiate the level calibration procedure.
3. Connect the signal generator's RF OUTPUT to the power meter.
4. Set the appropriate power meter calibration factor (if required) and zero the power meter.
5. Use the edit knob to change the adjustment value until the power meter reads +10 dBm.
6. Press the  key twice to store the new data.

### Remote Level Calibration Procedure

4-14.

The following paragraphs describe the remote level calibration procedure, the remote commands needed for this procedure, and the elements required to build a functioning controller program. Refer to Remote Calibration, earlier in the section, for general information about remote calibration.

A sample controller program for the remote level calibration procedure is contained in Appendix G. The program is written in Fluke BASIC and is provided as an example of the programs that will run on a Fluke 1722A controller.

Table 4-4 provides information needed to create a remote calibration program. This table lists specific commands that must be included in the level calibration program. Table 5B-3 in Section 5B of the Operator Manual describes the syntax of each command.

Figure 4-4 outlines the operation of the program in this procedure.

Proceed as follows to initiate the remote level calibration procedure:

1. Set the rear panel CAL|COMP switch to 1 (on) position.
2. Initiate the bus controller program.

Table 4-4. Remote Programming Commands for Level Calibration Procedure

COMMANDS	DESCRIPTION
CAL_LEVEL	Initiate the remote level calibration procedure
CC_RDPOWER	Send the power meter reading to the 6082A
CC_FREQ?	Request the RF frequency
CC_TARGET?	Request the target value
RFOUT	Program the RF output on/off
CC_SAVE	Save the measured data
CC_EXIT	Abort the cal procedure immediately
ERROR?	Request the rejected entry status
STATUS/STATUS?	Load/Request the overrange/uncal status

```

Initiate the level calibration procedure with "CAL_LEVEL"
Initialize power meter

Main Loop
  Request the RF frequency with "CC_FREQ?"

  If( frequency = 9e9) goto DONE

  Read power meter
  Send reading to 6082A with "CC_RDPOWER"

  Goto Main Loop

DONE
Store new data in calibration memory with "CC_SAVE"
End

```

Figure 4-4. Basic Structure of Level Calibration Program

The bus controller initiates the procedure by sending out the CAL\_LEVEL command. The controller requests the signal generator's center frequency with the CC\_FREQ? command and waits for a response.

When the signal generator responds, the controller gets a power meter reading and sends it to the signal generator with the CC\_RDPOWER command. The controller program ensures that each reading is settled before sending the reading to the signal generator.

Each time the signal generator receives a reading from the controller, it adjusts its internal settings and programs the new level. The program remains in the main loop until the signal generator receives two consecutive readings within 0.01 dB of the target value (10.00 dBm). The signal generator then considers the displayed adjustment value correct and returns the end code "9E+09, HZ" in response to the CC\_FREQ? command.

The program exits the main loop and saves the data by sending out the CC\_SAVE command.

## REFERENCE OSCILLATOR CALIBRATION

4-15.

The reference oscillator calibration procedures perform a single-point calibration of the internal 10-MHz reference oscillator. A frequency counter is connected to the 6082A's RF OUTPUT, and the reference oscillator calibration factor is adjusted based on the counter reading. The following lists the specific parameters of this procedure:

- Adjustment Range: 256 counts (6 ppm minimum)
- Adjustment Resolution: 1 count
- Target Value: 100 MHz
- RF Frequency: 100 MHz
- External Equipment: Frequency Counter (Fluke 1953A or equivalent)

When performing the front panel procedure, use the edit knob to adjust the calibration factor until the measured frequency matches the target value. During the remote calibration procedure, a program running on an IEEE-488 bus controller directs the procedure.

Both the front panel and remote calibration procedures reconfigure the front panel display in the following ways: the target level displays in the modulation field, the RF frequency displays in the frequency field, the adjustment value displays in the amplitude field, and the CAL annunciator lights.

The signal generator saves a copy of all adjustment values in temporary memory until it receives the store command. After receiving the store command, the signal generator calculates the internal calibration factor from the displayed adjustment value stores it in the calibration memory.

### NOTE

*This procedure can be used only to adjust the frequency of the internal reference oscillator. It cannot be used to adjust the frequency of the optional high-stability or medium-stability references (Options -130 and -132).*

## Front Panel Reference Oscillator Calibration Procedure

4-16.

The display is reconfigured for the procedure. Several of the front panel controls are disabled or operate differently than they normally do.

Table 4-1 lists the active front panel controls and describes the function of each.

Proceed as follows to execute the front panel reference oscillator calibration procedure:

1. Set the rear panel CAL|COMP switch to the 1 (on) position.
2. Enter special function 994 to initiate the oscillator calibration procedure.
3. Connect the 6082A's RF OUTPUT to the FLUKE 1953A's FREQA input.

4. Select the FREQA input, 1 second gate time, and the continuous trigger mode.
5. Use the edit knob to change the adjustment value until the counter reads 100 MHz.
6. Press the  key twice to store the new data.

### Remote Reference Oscillator Calibration Procedure

4-17.

The following paragraphs describe the remote reference oscillator calibration procedure, the remote commands needed for this procedure, and the elements required to build a functioning controller program. Refer to Remote Calibration, earlier in this section, for general information about remote calibration.

A sample controller program for the remote reference oscillator calibration procedure is contained in Appendix G. The program is written in Fluke BASIC and is provided as an example of the programs that will run on a Fluke 1722A controller.

Table 4-5 provides information needed to create a remote calibration program. This table lists specific commands that must be included in the reference oscillator calibration program. Table 5B-3 in Section 5B of the Operator Manual describes the syntax of each command.

Table 4-5. Remote Programming Commands for Reference Oscillator

COMMANDS	DESCRIPTION
CAL_REFOSC	Initiate the remote reference oscillator calibration pr
CC_RDFREQ	Send the counter reading to the 6082A
CC_FREQ?	Request the RF frequency
CC_TARGET?	Request the target value
RFOUT	Program the RF output on/off
CC_SAVE	Save the measured data
CC_EXIT	Abort the cal proce → immediately
ERROR?	Request the rejected entry status
STATUS/STATUS?	Load/Request the overrange/uncal status

Figure 4-5 outlines the operation of the program in this procedure.

Proceed as follows to initiate the remote reference oscillator calibration procedure:

1. Set the rear panel CAL|COMP switch to 1 (on) position.
2. Initiate the bus controller program.

The bus controller initiates the calibration procedure by sending out the CAL\_REFOSC command. The controller requests the center frequency of the signal generator with the CC\_FREQ? command and waits for a response.

When the signal generator responds, the controller gets a counter reading, ensures that the reading is settled, and sends it to the signal generator with the command CC\_RDFREQ.

## CLOSED-CASE CALIBRATION

```
Initiate the reference oscillator calibration procedure with "CAL_REFOSC"  
Initialize frequency counter  
  
Main Loop  
  Request the RF frequency with "CC_FREQ?"  
  
  If( frequency ≈ 9e9) goto DONE  
  
  Read frequency counter  
  Send reading to 6082A with "CC_RDFREQ"  
  
  Goto Main Loop  
  
DONE  
Store new data in calibration memory with "CC_SAVE"  
End
```

Figure 4-5. Basic Structure of the Reference Oscillator Calibration Program

Each time the signal generator receives a reading from the controller, it adjusts its internal settings and programs the new reference oscillator DAC setting.

The program remains in the main loop until the signal generator receives two consecutive readings within 10 Hz of the target value (100 MHz). At that point, the signal generator considers the displayed adjustment value correct and returns the end code "9E+09, HZ" in response to the CC\_FREQ? command.

The program exits the main loop and saves the data by sending out the CC\_SAVE command.

# Section 5

## Access Procedures

### INTRODUCTION

5-1.

Section 5 describes access procedures for the following major assemblies:

- Front Panel Section
- Rear Panel Section
- A2 Coarse Loop PCA
- A3 Subsynthesizer VCO PCA
- A4 Subsynthesizer PCA
- A5 Coarse Loop VCO PCA
- A6 Mod Oscillator PCA
- A9 Sum Loop VCO PCA
- A12 Sum Loop PCA
- A13 Controller PCA
- A14 FM PCA
- A22 Delay Line Assembly
- A31 Output PCA
- A32 Premodulator PCA
- A33 Modulation Control PCA
- A35 Attenuator/RPP Assembly

Some assemblies found in the Signal Generator are not listed here because access descriptions are not required to remove them.

### SAFETY

5-2.

Read the following paragraphs for important information on how to safely access the assemblies in the Signal Generator.

Refer to the safety sheet at the front of the manual for additional safety information.

#### WARNING

**TO AVOID ELECTRIC SHOCK, DISCONNECT THE POWER CORD BEFORE REMOVING COVERS FROM THE SIGNAL GENERATOR.**

The Signal Generator remains energized when the POWER switch is in the STBY position. Before accessing circuit boards, disconnect ac power by unplugging the power cord from the rear panel power receptacle before removing protective panels, replacing components, or soldering.

Some components and assemblies in the Signal Generator are susceptible to damage from electrostatic discharge. Refer to the parts lists in Section 8. Static sensitive components and assemblies are marked with an asterisk (\*).

Refer to the Static Awareness sheet that appears at the front of this section for guidelines on proper handling of static sensitive devices.

**PIVOTING SYNTHESIZER MODULE WARNING** **5-3.**

To gain access to many of the circuit boards in the synthesizer module, you must raise a pivoting module. This synthesizer module is heavy and could cause severe injury if it were to drop unexpectedly. A gas strut holds the module in the raised position while the unit is being serviced. When raising or lowering the module, observe the following warning to avoid injury.

**WARNING**

**THE SYNTHESIZER MODULE IS HEAVY AND MAY CAUSE INJURY IF IT COLLAPSES. READ THE INSTRUCTIONS ON THE DECAL AFFIXED TO THE MODULE OR THE PROCEDURE IN THIS MANUAL BEFORE RAISING THE MODULE. TEST THE GAS STRUT SUPPORT BY ATTEMPTING TO CLOSE THE MODULE RAPIDLY. THE STRUT SHOULD RESIST RAPID CLOSING OF THE MODULE.**

A decal on the synthesizer module and the text under "Raising and Lowering the Synthesizer Module" describe the correct method of opening and closing the module. Read that information before attempting to raise the pivoting module.

**LOCATION OF MAJOR ASSEMBLIES** **5-4.**

In Section 8, List of Replaceable Parts, illustrations show the location of the major assemblies of the Signal Generator.

Refer to Section 6, Circuit Descriptions, Troubleshooting, and Alignment for information on exchanging modules.

**ACCESS INSTRUCTIONS** **5-5.**

Access instructions for some assemblies of the 6082A Signal Generator are provided in the following paragraphs.

To install the assemblies, reverse the disassembly steps. Be certain the pin connectors and filter sockets are straight when replacing a printed circuit assembly (pca). Make sure that pca pulls and RF cables are not pinched between the modules and module covers.

**Removing the Front Panel Section** **5-6.**

Proceed as follows to remove the front panel section:

1. Remove the two #6 pan-head screws that attach the RF connector bracket to the output module near the A35 Attenuator assembly. One screw is accessible from the top of the instrument, the other from the bottom.

2. Disconnect the RF output cable W1 from the Type "N" RF OUTPUT connector J1.
3. Remove the decals from both front panel handles. (Removing the decals ruins them. To restore instrument appearance to new condition, attach new decals when reassembling. The decal part number is listed in Section 8, Table 8-1.)
4. Remove the five flat-head screws from each front panel handle, and slide the front panel forward.
5. Disconnect power ribbon cable W20 and controller ribbon cables W18 and W36 from the front panel A1 Display PCA.
6. Disconnect the inner part of the BNC connectors on the mod input and mod output cables W2, W3, W4, and W5.

### Removing the Rear Panel Section

5-7.

Proceed as follows to remove the rear panel section:

1. Disconnect the synthesizer and output module power cables W22 and W23, and the front panel power cable W20 from the A15 Power Supply PCA.
2. Disconnect the controller-IEEE ribbon cable W17 from the A16 IEEE PCA.
3. Disconnect the REF IN and REF OUT RF cables W6 and W7 from the synthesizer module.
4. Remove the decals from both rear panel handles. (Removing the decals ruins them. To restore instrument appearance to new condition, attach new decals when reassembling. The decal part number is listed in Section 8, Table 8-1.)
5. Remove the five flat-head screws from each handle. Remove the rear panel section.

### Raising and Lowering the Synthesizer Module

5-8.

The synthesizer module, which must be raised to gain access to many of the circuit boards, is very heavy. For protection, a gas strut is installed to support the module. The top (synthesizer) module pivots up to allow access to all parts of the Signal Generator. To avoid injury when raising or lowering the module, read the following warning and observe the following procedures.

#### WARNING

**THE SYNTHESIZER MODULE IS HEAVY AND MAY CAUSE INJURY IF IT COLLAPSES. READ THE INSTRUCTIONS ON THE DECAL AFFIXED TO THE MODULE OR THE FOLLOWING PROCEDURE BEFORE RAISING THE MODULE. TEST THE GAS STRUT SUPPORT BY ATTEMPTING TO RAPIDLY CLOSE THE MODULE. THE STRUT SHOULD RESIST RAPID CLOSING OF THE MODULE.**

Proceed as follows to raise the synthesizer module:

1. Remove the three #8 pan-head screws that secure the module to the chassis sides.
2. Grasp the handle and lift the module.
3. Lock the module in the up position by inserting two of the previously removed #8 screws into the bosses protruding from the chassis sides near the hinges.

Proceed as follows to lower the synthesizer module:

1. Support the module in the raised position and remove the two lock-up screws.
2. Keep hands clear and use the handle to lower the module.
3. Lock the module in the down position using the three #8 pan-head screws.

**CAUTION**

**THE GAS STRUT CAN SWING THE SYNTHESIZER MODULE OPEN WHEN THE INSTRUMENT IS TURNED ON ITS SIDE. TO AVOID THIS, ALWAYS LOCK THE SYNTHESIZER MODULE IN THE DOWN POSITION AFTER LOWERING IT.**

**Removing the A2 Coarse Loop PCA**

**5-9.**

Proceed as follows to remove the A2 Coarse Loop PCA:

1. Disconnect RF cables W6, W7, and W15 from the connectors at the rear of the synthesizer module, and remove the nuts and lock washers from the connectors.

**WARNING**

**THE SYNTHESIZER MODULE IS HEAVY AND MAY CAUSE INJURY IF IT COLLAPSES. READ THE INSTRUCTIONS ON THE DECAL AFFIXED TO THE MODULE OR THE PROCEDURE IN THIS MANUAL BEFORE RAISING OR LOWERING THE MODULE.**

2. Raise the synthesizer module.
3. Remove the #6 screws holding the bottom synthesizer module cover, and remove the cover.
4. Remove plug-in capacitor C1 and resistor R1, which are between the A22 Delay Cable assembly and the A2 Coarse Loop PCA.

**NOTE**

*When reinstalling C1, be certain to put it between J1 on the A22 Delay Cable assembly and J9 on the A2 Coarse Loop. J2 on A22 and J10 on the A2 PCA are not used.*

5. Remove the #6 screws holding the heat sinks on U305 and U310, and remove the heat sinks.

6. Remove the #6 screws holding the PCA.
7. Carefully remove the A2 Coarse Loop PCA.

### Removing the A3 Subsynthesizer VCO PCA

5-10.

Proceed as follows to remove the A3 Subsynthesizer VCO PCA:

1. Disconnect RF cable W13 from the connector at the front of the synthesizer module, and remove the nut and lock washer from the connector.

#### WARNING

**THE SYNTHESIZER MODULE IS HEAVY AND MAY CAUSE INJURY IF IT COLLAPSES. READ THE INSTRUCTIONS ON THE DECAL AFFIXED TO THE MODULE OR THE PROCEDURE IN THIS MANUAL BEFORE RAISING OR LOWERING THE MODULE.**

2. Raise the synthesizer module.
3. Remove the #6 screws holding the bottom synthesizer module cover, and remove the cover.
4. Remove the #6 screws holding the PCA.
5. Carefully remove the A3 Subsynthesizer VCO PCA.

### Removing the A4 Subsynthesizer PCA

5-11.

Proceed as follows to remove the A4 Subsynthesizer PCA:

1. Remove the #6 screws holding the top synthesizer module cover, and remove the cover. (The #10 screws are adjustment-access screws and need not be removed.)
2. Remove the #6 screws holding the PCA.
3. Carefully remove the A4 Subsynthesizer PCA.

### Removing the A5 Coarse Loop VCO PCA

5-12.

Proceed as follows to remove the A5 Coarse Loop VCO PCA:

#### WARNING

**THE SYNTHESIZER MODULE IS HEAVY AND MAY CAUSE INJURY IF IT COLLAPSES. READ THE INSTRUCTIONS ON THE DECAL AFFIXED TO THE MODULE OR THE PROCEDURE IN THIS MANUAL BEFORE RAISING OR LOWERING THE MODULE.**

1. Raise the synthesizer module.
2. Disconnect RF cable W14 from the connector at the front of the synthesizer module, and remove the nut and lock washer from the connector.

3. Lower the synthesizer module.
4. Remove the #6 screws holding the top synthesizer module cover, and remove the cover. (The #10 screws are adjustment-access screws and need not be removed.)
5. Remove the #6 screws holding the PCA.
6. Carefully remove the A5 Coarse Loop VCO PCA.

**Removing the A6 Mod Oscillator PCA**

**5-13.**

Proceed as follows to remove the A6 Mod Oscillator PCA:

1. Remove the #6 screws holding the top synthesizer module cover, and remove the cover. (The #10 screws are adjustment-access screws and need not be removed.)
2. Remove the #6 screws holding the PCA.
3. Carefully remove the A6 Mod Oscillator PCA.

**Removing the A31 Output PCA**

**5-14.**

Proceed as follows to remove the A31 Output PCA:

**WARNING**

**AVOID PERSONAL INJURY. THE SYNTHESIZER MODULE IS HEAVY; BE FAMILIAR WITH THE INSTRUCTIONS IN PARAGRAPH 5-8 BEFORE PERFORMING THE FOLLOWING PROCEDURE.**

1. Raise the synthesizer module.
2. Disconnect RF cable W15 from the connector at the back of the output module, and remove the nut and lock washer from the connector.
3. Lower the synthesizer module.
4. Remove the #6 screws holding the bottom output module cover, and remove the cover. (The #10 screws are adjustment-access screws and need not be removed.)
5. Disconnect the RF cable, which is part of the A31 Output PCA, from the A32 Premodulator PCA.
6. Disconnect the two mod control-output ribbon cables W33 and W35 from the Output PCA.
7. Remove the #6 screws holding the output amplifier cover, and remove the cover.
8. Remove the #6 screws holding the output barrier.
9. Remove the remaining #6 screws holding the PCA. Do not remove the #4 screws that are in the output amplifier area.
10. Carefully remove the A31 Output PCA.

**Removing the A9 Sum Loop VCO PCA****5-15.**

Proceed as follows to remove the A9 Sum Loop VCO PCA:

1. Remove the #6 screws holding the bottom output module cover, and remove the cover. (The #10 screws are adjustment-access screws and need not be removed.)
2. Remove plug-in capacitor C1 between the A32 Premodulator PCA and the A9 Sum Loop VCO PCA.
3. Remove the #6 screws holding the PCA.
4. Carefully remove the A9 Sum Loop VCO PCA.

**Removing the A32 Premodulator PCA****5-16.**

Proceed as follows to remove the A32 Premodulator PCA:

1. Remove the #6 screws holding the bottom output module cover, and remove the cover. (The #10 screws are adjustment-access screws and need not be removed.)
2. Disconnect the RF cable, which is part of the A31 Output PCA, from the A32 Premodulator PCA.
3. Disconnect mod control-premodulator ribbon cable W34 from the A32 Premodulator PCA.
4. Remove plug-in capacitor C1 between the A32 Premodulator PCA and the A9 Sum Loop VCO PCA.
5. Remove the #6 screws holding the PCA.
6. Carefully remove the A32 Premodulator PCA.

**Removing the A33 Modulation Control PCA****5-17.**

Proceed as follows to remove the A33 Modulation Control PCA:

1. Remove the #6 screws holding the bottom output module cover, and remove the cover. (The #10 screws are adjustment-access screws and need not be removed.)
2. Disconnect mod control-premodulator ribbon cable W34 from the A33 Mod Control PCA.
3. Disconnect mod control-output ribbon cables W33 and W35 from the A33 Mod Control PCA.
4. Remove the #6 screws holding the PCA.
5. Carefully remove the A33 Modulation Control PCA.

### Removing the A12 Sum Loop PCA

5-18.

Proceed as follows to remove the A12 Sum Loop PCA:

1. Disconnect RF cables W13 and W14 from the connectors at the front edge of the output module, and remove the nuts and lock washers from the connectors.

#### WARNING

**THE SYNTHESIZER MODULE IS HEAVY AND MAY CAUSE INJURY IF IT COLLAPSES. READ THE INSTRUCTIONS ON THE DECAL AFFIXED TO THE MODULE OR THE PROCEDURE IN THIS MANUAL BEFORE RAISING OR LOWERING THE MODULE.**

2. Raise the synthesizer module.
3. Remove the #6 screws holding the top output module cover, and remove the cover. (The #10 screws are adjustment-access screws and need not be removed.)
4. Disconnect FM-sum loop ribbon cable W32 from the A12 Sum Loop PCA.
5. Remove plug-in capacitor C2 between the A12 Sum Loop PCA and the A14 FM PCA.
6. Remove the #6 screws holding the sum loop lid, and remove the lid.
7. Remove the #6 screws holding the PCA.
8. Carefully remove the A12 Sum Loop PCA.

### Removing the A13 Controller PCA

5-19.

Proceed as follows to remove the A13 Controller PCA:

#### WARNING

**THE SYNTHESIZER MODULE IS HEAVY AND MAY CAUSE INJURY IF IT COLLAPSES. READ THE INSTRUCTIONS ON THE DECAL AFFIXED TO THE MODULE OR THE PROCEDURE IN THIS MANUAL BEFORE RAISING OR LOWERING THE MODULE.**

1. Raise the synthesizer module.
2. Remove the #6 screws holding the top output module cover, and remove the cover. (The #10 screws are adjustment-access screws and need not be removed.)
3. Disconnect front panel display ribbon cables W18 and W36 from the A13 Controller PCA.
4. Disconnect IEEE ribbon cable W17 from the A13 Controller PCA.
5. Disconnect controller-synthesizer ribbon cable W16 from the A13 Controller PCA.

6. Disconnect power supply cable W22 from the A13 Controller PCA.
7. Disconnect relay driver ribbon cable W19 from the A13 Controller PCA.
8. Remove the #6 screws holding the PCA.
9. Carefully remove the A13 Controller PCA.

### Removing the A14 FM PCA

5-20.

Proceed as follows to remove the A14 FM PCA:

#### WARNING

**THE SYNTHESIZER MODULE IS HEAVY AND MAY CAUSE INJURY IF IT COLLAPSES. READ THE INSTRUCTIONS ON THE DECAL AFFIXED TO THE MODULE OR THE PROCEDURE IN THIS MANUAL BEFORE RAISING OR LOWERING THE MODULE.**

1. Raise the synthesizer module.
2. Remove the #6 screws holding the top output module cover, and remove the cover. (The #10 screws are adjustment-access screws and need not be removed.)
3. Disconnect FM-sum loop ribbon cable W32 from the A14 FM PCA.
4. Remove plug-in capacitor C2 between the A12 Sum Loop PCA and the A14 FM PCA.
5. Remove the #6 screws holding the PCA.
6. Carefully remove the A14 FM PCA.

### Removing the A35 Attenuator/RPP Assembly

5-21.

Proceed as follows to remove the A35 Attenuator/RPP Assembly:

#### WARNING

**THE SYNTHESIZER MODULE IS HEAVY AND MAY CAUSE INJURY IF IT COLLAPSES. READ THE INSTRUCTIONS ON THE DECAL AFFIXED TO THE MODULE OR THE PROCEDURE IN THIS MANUAL BEFORE RAISING OR LOWERING THE MODULE.**

1. Raise the synthesizer module.
2. Disconnect the RF output cable W1 at the Attenuator.
3. Disconnect controller-relay driver ribbon cable W19 from A35.
4. Remove the 13 #6 screws holding the Attenuator.

## Removing the A22 Delay Cable Assembly

5-22.

Proceed as follows to remove the A22 Delay Cable Assembly:

### WARNING

**THE SYNTHESIZER MODULE IS HEAVY AND MAY CAUSE INJURY IF IT COLLAPSES. READ THE INSTRUCTIONS ON THE DECAL AFFIXED TO THE MODULE OR THE PROCEDURE IN THIS MANUAL BEFORE RAISING OR LOWERING THE MODULE.**

1. Raise the synthesizer module.
2. Remove the #6 screws holding the bottom synthesizer module cover, and remove the cover.
3. Remove plug-in capacitor C1 and resistor R1, which are between the A22 Delay Cable PCA and the A2 Coarse Loop PCA.

### NOTE

*When reinstalling C1, make sure to put it between J1 on the A22 Delay Cable assembly and J9 on the A2 Coarse Loop. J2 on A22 and J10 on the A2 PCA are not used.*

4. Remove the four #6 screws holding the A25 Discriminator PCA. Do not remove the screws holding the clamp that attaches the delay line to the PCA.
5. Remove the two #6 screws holding the lower delay cable retainer.
6. Remove the two #6 screws holding the upper delay cable retainer that holds the A26 Delay Cable PCA in place. Do not remove the screws holding the clamp that attaches the delay line to the PCA; do not disconnect the SMA connector on the semi-rigid trim cable.
7. Remove the A22 Delay Line assembly.

# Section 6

## Circuit Description, Troubleshooting, and Alignment

### INTRODUCTION

6-1.

Section 6 describes the component-level circuit operation of the 6082A Synthesized RF Signal Generator. In addition, this portion of the manual includes troubleshooting information and procedures for adjusting the circuit assemblies.

There are seven parts to Section 6: 6A through 6F, and this introductory section. Sections 6A through 6F are laid out similarly to each other. Each section contains a detailed circuit description, followed by troubleshooting information, and finally by adjustment procedures where they apply.

This introductory section presents additional information needed to replace assemblies, perform tests, decipher codes, and understand diagnostic functions. Since the information in these paragraphs applies to Sections 6A through 6E, we recommend that you read the rest of this section before proceeding. This section covers the following major topics:

- Troubleshooting the 6082A

General troubleshooting practices and information as they relate to the 6082A, plus parts replacement information.

- Module Replacement

Procedures for obtaining a replacement module, including part numbers for the assemblies. Also brief overview of adjustments necessary for each module.

- Updating Compensation Memory With Module Exchange Data

A procedure for transferring the compensation data to the new EPROM after exchanging a module.

- Self Tests Descriptions

Explanation of the power-up self tests and their codes.

- Status Signals and Status Codes

A listing of hardware status signals and their codes.

## CIRCUIT DESCRIPTION, TROUBLESHOOTING, AND ALIGNMENT

- Software Diagnostic Functions

Descriptions of the built-in diagnostic functions.

Once you have determined the cause of the failure, proceed in one of the following three ways:

1. Return the failed Signal Generator to an authorized Fluke Service Center (refer to Section 8 for Service Center locations).
2. Identify the failed module and replace it through the Module Exchange Center (refer to the Module Replacement paragraph in this section.)
3. Troubleshoot and replace the failed components. Refer to Section 9 for part numbers and other ordering information when ordering components.

Refer to the information in the rest of this section to help you determine which module or component has failed.

### **TROUBLESHOOTING THE 6082A**

**6-2.**

Signal generator failures may be caused by any of several conditions: operator error, out-of-specification performance, or by catastrophic failure. The functional block diagram, Figure 6-1, and the troubleshooting tree, Figure 6-2 will aid you in determining the cause of the Signal Generator malfunction.

Once you have isolated the problem to a specific area or circuit, the functional descriptions in Section 2, the information contained in this section, and the schematics in Section 8 will help you isolate the defective module or component. The Signal Generator must perform according to the specifications in Table 1-1 to be considered repaired and working properly.

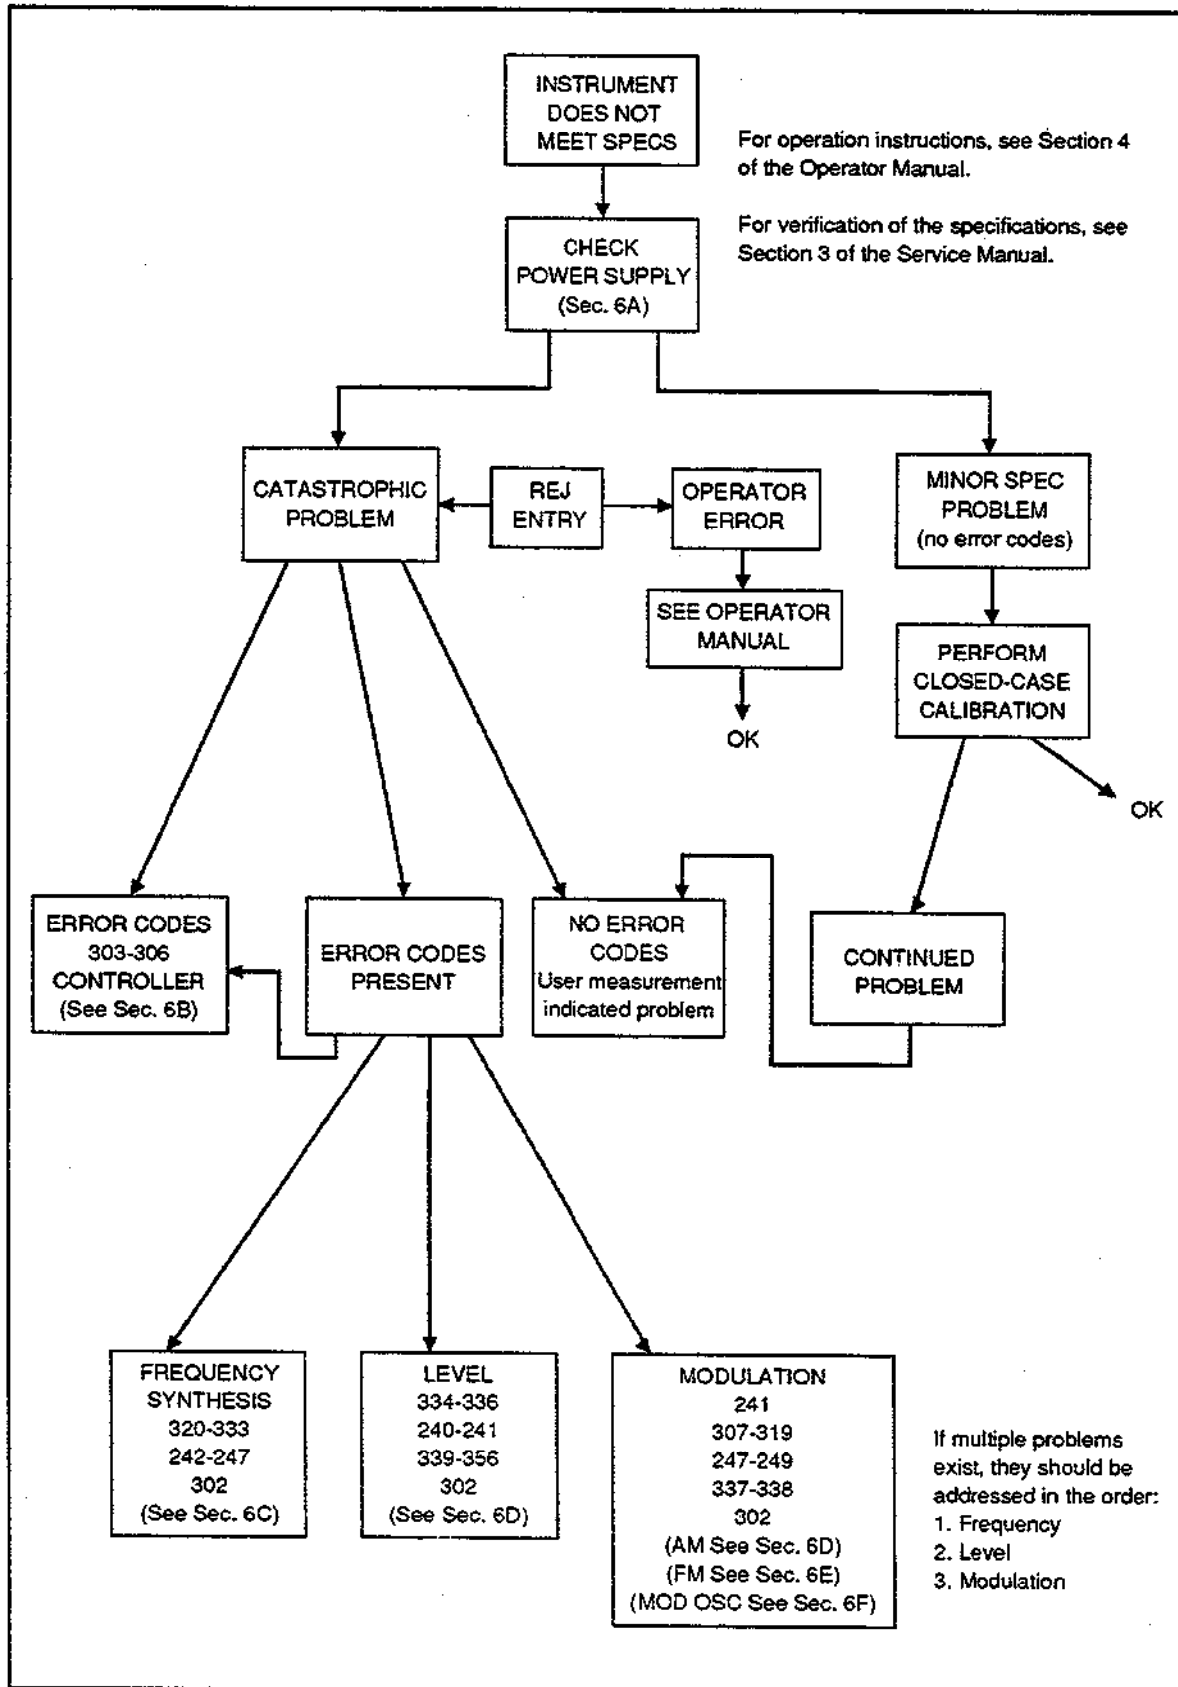

Most operator errors are indicated by either a steady or flashing STATUS indicator or by the REJ ENTRY front panel display annunciator. However, some operator errors are not indicated this way, and may be mistaken for out-of-specification conditions. If you suspect an operator error, review the operating instructions in the Operator Manual.

Use the performance tests (Section 3, Performance Tests) to determine which parameters need adjustment. You can usually correct out-of-specification performance by performing the appropriate calibration procedure. (Refer to Section 4, Closed-Case Calibration.)

If the problem is not caused by an operator error and cannot be corrected by calibration, the Signal Generator has suffered a catastrophic failure. The status and self test failure codes usually provide a good indication of the cause of the failure. Use the troubleshooting tree along with the detailed troubleshooting information and the performance tests to help isolate the failure.

**CIRCUIT DESCRIPTION, TROUBLESHOOTING, AND ALIGNMENT**

**Figure 6-2. Instrument Troubleshooting Tree**

**Parts Replacement****6-3.**

Most parts are replaced using ordinary methods. However, when replacing surface-components, use a 600° F soldering iron (such as an Ungar 50T7) with a number 76 heater, a number 88 tip, and 2% silver solder paste (such as Electro Science Fabrication SP-37D1, or similar wire solder).

See appropriate sections of this manual for information on components that require alignment, compensation, and/or calibration when they are replaced. Use the performance tests in Section 3 to verify the results of the repairs.

Refer to Section 7 for part numbers and other ordering information when ordering components.

**MODULE REPLACEMENT****6-4.**

Figure 6-3, Assembly Location Block Diagram, illustrates the physical layout of the 6082A assemblies. This layout indicates how the pca's are interconnected and illustrates signal flow between assemblies.

To order a replacement module through the Module Exchange Center, use Table 6-1 to locate the part number for the assembly. This table identifies all assemblies that are available as a module exchange part.

Table 6-1. 6082A Module Exchange Assemblies

ASSEMBLY NO.	MEC P/N	DESCRIPTION
A1	882068	Display PCA
A2	882071	Coarse Loop PCA
A3	882076	Subsynthesizer VCO PCA
A4	882084	Subsynthesizer PCA
A5	882089	Coarse Loop VCO PCA
A6	882097	Mod Oscillator PCA
A7	882022	Relay Driver PCA
A9	882035	Sum Loop VCO PCA
A12	882043	Sum Loop PCA
A13	882048	Controller PCA
A14	882050	FM Board PCA
A15	882100	Power Supply PCA
A19	860858	Switch PCA
A22	860887	Delay Line Assembly (A25+A26+Delay Cable+Trim Cable)
A31	882331	Output PCA
A32	882118	Premodulator PCA
A33	882121	Mod Control PCA
A35	882027	Attenuator/RPP Assembly (A7+A34+A30)

CIRCUIT DESCRIPTION, TROUBLESHOOTING, AND ALIGNMENT

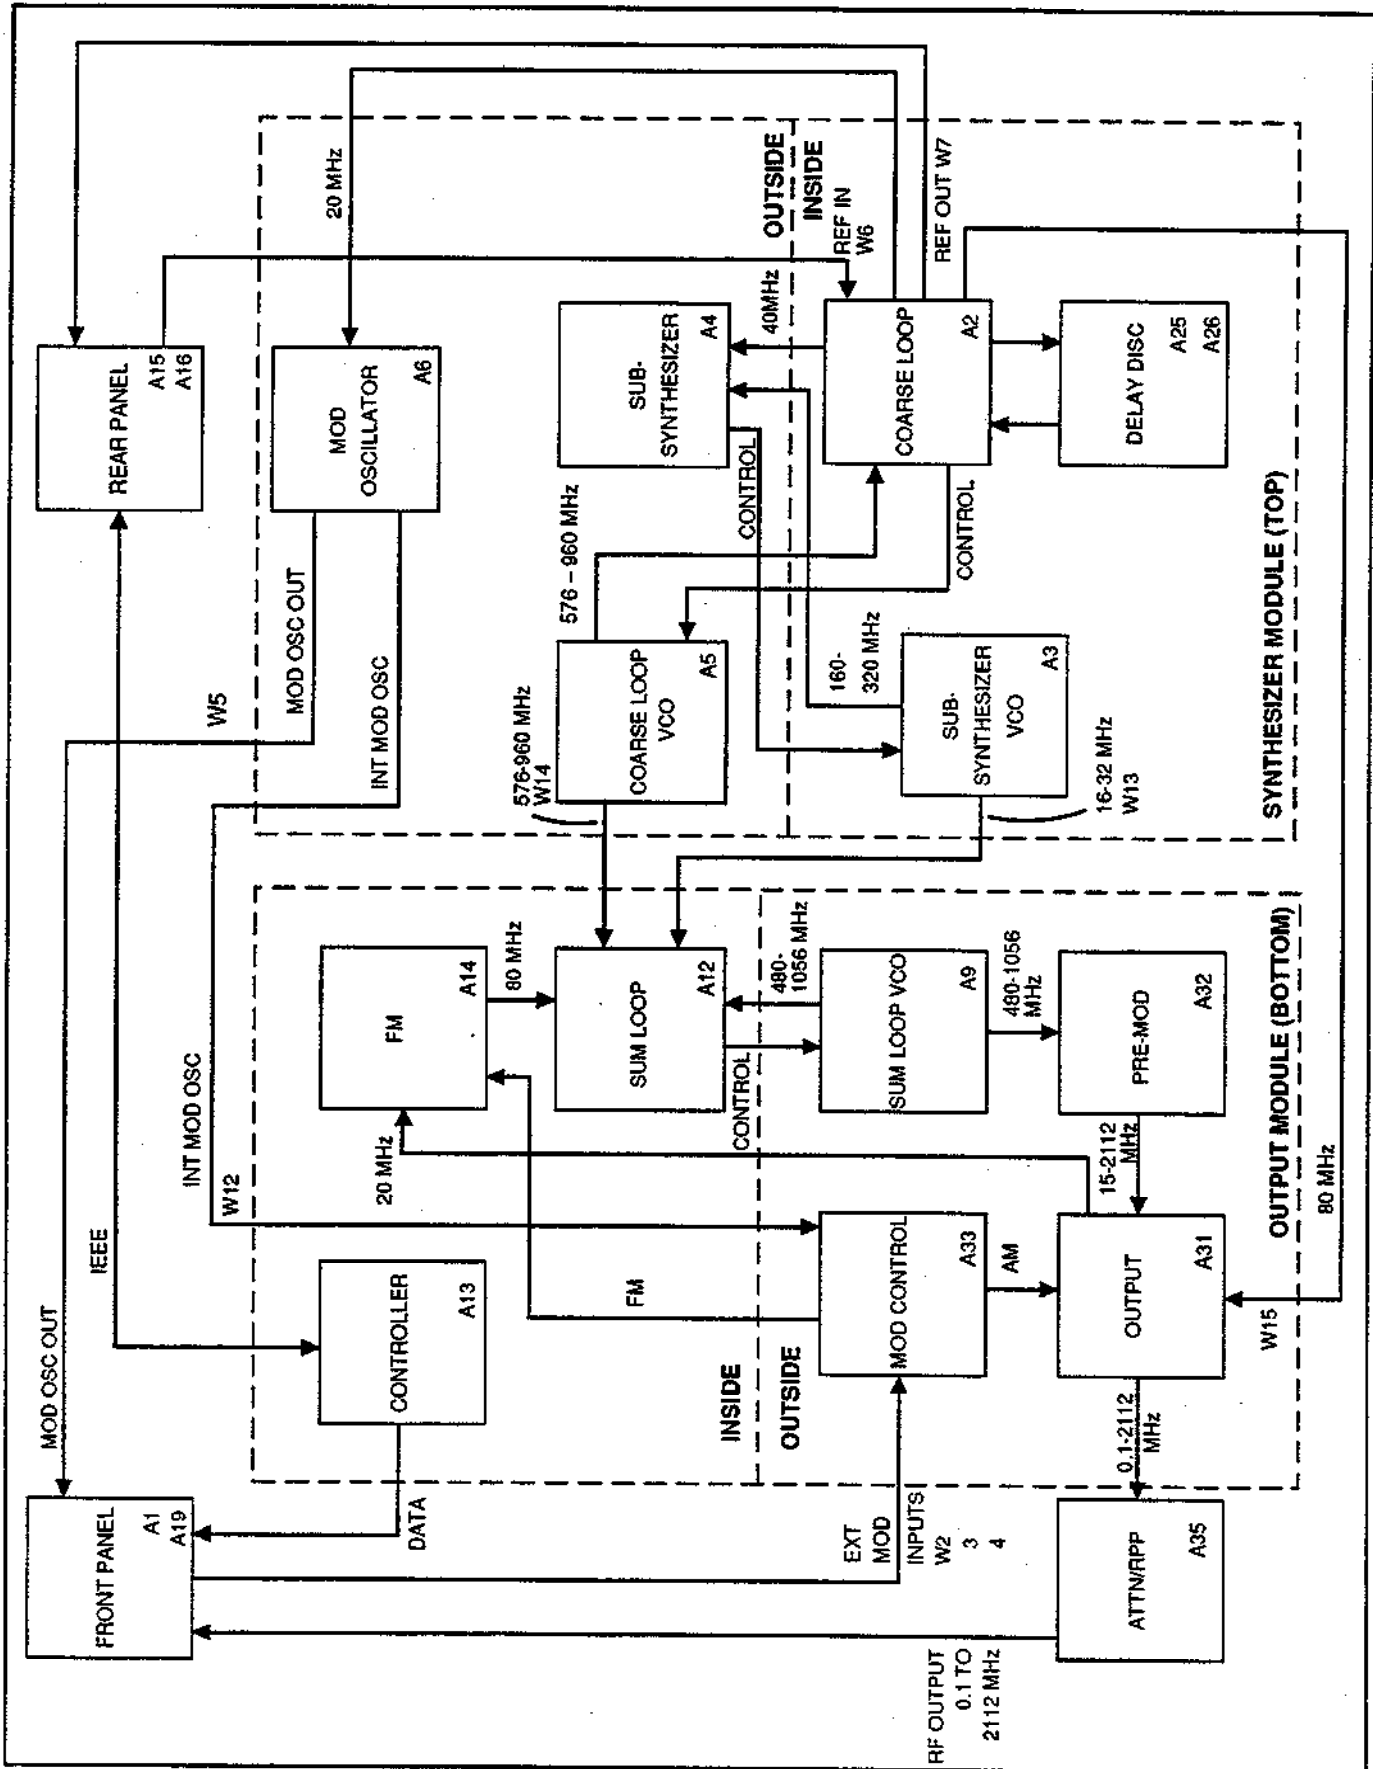

Figure 6-3. Assembly Location Block Diagram

The access procedures in Section 5 provide instructions for removing and replacing the modules. The paragraphs under the Module Replacement major heading briefly describe the available exchange modules and state whether adjustments are necessary after installing them in the Signal Generator. Refer to Sections 6A through 6F for details on troubleshooting mount and aligning the modules.

After replacing (and aligning if necessary) a module, proceed to Section 3 and perform the related performance tests to ensure that the failure has been fixed.

After verifying that the replacement module corrects the problem, pack the failed module in the shipping container (use the prepaid return shipping papers and label), and return it to your nearest Fluke Service Center.

**A1 Display PCA** **6-5.**

Adjustments: None.

**A2 Coarse Loop PCA** **6-6.**

Adjustments: None.

Perform Reference Oscillator Calibration as described under the heading with the same title in Section 4.

**A3 Subsynthesizer VCO PCA** **6-7.**

Adjustments: R106 on Subsynthesizer PCA. See "SSB Mixer LO Drive Adjustment, R106" in Section 6C.

A compensation data EPROM containing VCO tuning data is included. See "Updating Compensation Memory With Module Exchange Data" in this section for data transfer instructions.

**A4 Subsynthesizer PCA** **6-8.**

Adjustments: R106. See "SSB Mixer LO Drive Adjustment, R106" in Section 6C.

Perform Reference Oscillator Calibration as described under the heading with the same title in Section 4.

**A5 Coarse Loop VCO PCA** **6-9.**

Adjustments: None.

Perform Coarse Loop compensation as described in Section 7.

**A6 Mod Oscillator PCA** **6-10.**

Adjustments: None.

**A7 Relay Driver PCA** **6-11.**

Adjustments: None.

### **A31 Output PCA**

**6-12.**

Adjustments:

- R28, detector offset/linearity. See “Mod Control PCA Detector Offset Adjustment, R28, and Low Level Linearity Adjustment, R55” in Section 6D.
- R55, low level linearity. See “Mod Control PCA Detector Offset Adjustment, R28, and Low Level Linearity Adjustment, R55” in Section 6D.
- R20, RF Level adjustment. See “Mod Control PCA RF Level Adjustment, R20” in Section 6D.
- R10, AM Depth adjustment. See “Mod Control PCA AM Depth Adjustment, R10” in Section 6D.

A compensation data EPROM containing Output PCA level correction data is included. See “Updating Compensation Memory With Module Exchange Data” in this section for data transfer instructions.

### **A9 Sum Loop VCO PCA**

**6-13.**

Adjustments:

- R51, AM Bandwidth adjustment. See “Premodulator PCA Bandwidth Adjustment, R51” in Section 6D.
- R23, Amplifier gain adjustment. See “Sum Loop VCO Assembly Adjustment” in Section 6C.

Perform Sum Loop compensation as described in Section 7.

### **A32 Premodulator PCA**

**6-14.**

Adjustments: R51, AM Bandwidth adjustment. See “Premodulator PCA Bandwidth Adjustment, R51” in Section 6D.

### **A33 Modulation Control PCA**

**6-15.**

Adjustments:

- R28, detector offset/linearity. See “Mod Control PCA Detector Offset Adjustment, R28, and Low Level Linearity Adjustment, R55” in Section 6D.
- R55, low level linearity. See “Mod Control PCA Detector Offset Adjustment, R28, and Low Level Linearity Adjustment, R55” in Section 6D.
- R20, RF Level adjustment. See “Mod Control PCA RF Level Adjustment, R20” in Section 6D.
- R10, AM Depth adjustment. See “Mod Control PCA AM Depth Adjustment, R10” in Section 6D.

**A12 Sum Loop PCA****6-16.**

Adjustments:

- R23, Amplifier gain adjustment. See "Sum Loop VCO Assembly Adjustment" in Section 6C.
- R116, FM null adjustment. See "FM Null Adjustment, R116" in Section 6C.

**A13 Controller PCA****6-17.**

Adjustments: None.

To preserve the instrument calibration/compensation data, transfer the battery backed RAM IC U8 and the EEPROM U9 from the old Controller PCA to the replacement controller. If either U8 or U9 are bad, review "Calibration/Compensation Memory" (Section 6B) then replace the faulty IC.

**A14 FM Board PCA****6-18.**

Adjustments:

- R107, FM deviation high-rate. See "Alignment of FM PCA (A14)" in Section 6E.
- R39, HIDEV volts/steering. See "Alignment of FM PCA (A14)" in Section 6E.
- R35, LOWDEV volt/steering. See "Alignment of FM PCA (A14)" in Section 6E.
- R116 on Sum Loop PCA. See "FM Null Adjustment, R116" in Section 6C.

**A15 Power Supply PCA****6-19.**

Adjustments: None.

**A19 Switch PCA****6-20.**

Adjustments: None.

**A35 Attenuator/RPP Assembly (A7, A21, A30)****6-21.**

Adjustments: R20, RF Level. See "Mod Control PCA RF Level Adjustment, R20" in Section 6D.

A compensation data EPROM containing Attenuator/RPP level correction data is included. See "Updating Compensation Memory With Module Exchange Data" in this section for data transfer instructions.

**A22 Delay Line Assembly (A25, A26, Delay Cable, Trim Cable)****6-22.**

Adjustments: None.

## UPDATING COMPENSATION MEMORY WITH MODULE EXCHANGE DATA

6-23.

After installing the A35 Attenuator/RPP, A31 Output, or A3 Subsynthesizer VCO module exchange assemblies, load the data from the corresponding compensation EPROM into the compensation memory. The module exchange EPROM is installed in a socket on the A13 Controller PCA. Transfer the compensation data by one of three special functions, depending on which of the three assemblies has been replaced.

Perform the following steps to update the compensation memory with the new module exchange data:

1. Verify that the power to the 6082A Signal Generator is turned off.
2. Access the A13 Controller PCA as described by the access procedure in Section 5. Leave the controller in place with all cables attached since it must be operational.
3. Install the module exchange EPROM into the socket on the controller labeled U10.
4. Power up the 6082A.
5. Remove the sticker labeled "CAL|COMP" from the rear panel and set the CAL|COMP switch to the "1" position.
6. Verify that the CAL and COMP annunciators on the front panel are flashing.
7. Enter Special Function 961 to transfer the Attenuator/RPP data, Special Function 962 to transfer the Output data, or Special Function 963 to transfer the Subsynthesizer VCO data.
8. Respond to the prompt "Att Sto?", "Out Sto?" or "Sub Sto ?" by pressing the  key.

The message "—Sto—" is displayed for 12 seconds for the Attenuator, and 5 seconds for the Output and Subsynthesizer while the data is transferred.

### CAUTION

**Do not turn the POWER switch off or change the CAL|COMP switch until the store operation is complete. Doing so could damage the contents of the compensation memory.**

9. Set the rear panel CAL|COMP switch to the "0" position.
10. Verify that the CAL and COMP annunciators no longer flash.
11. Turn the power off and remove the module exchange EPROM, if desired.
12. Reassemble the instrument by reversing the disassembly steps.

**SELF TEST DESCRIPTION****6-24.**

The instrument self tests are automatically performed on power-up or when initiated by Special Function 02. If any test fails, the message "FAIL" displays along with the corresponding status code. A complete list of the test failures displays upon completion. Use the **STATUS** key to scroll the list if there are more than four failures.

During the tests, the RPP relay opens to protect instruments connected to the RF OUTPUT from possible damage. The RF output (334-336) and pulse modulator (337 and 338) tests are not performed at power-up or by Special Function 02 because signals as high as -20 dBm may be present at the RF output connector during these tests. Use Special Function 06 to perform a complete self-test including the RF output and pulse modulator tests.

Special Function 904 runs the self tests in a troubleshooting mode. The software stops after each test that fails, leaving the hardware in the test configuration and the error code in the display. The RF OUTPUT is enabled so measurement equipment can be connected. Press any key to continue the test.

The self test results (see Table 6-2) can be displayed by entering Special Function 03. Status code 00 indicates no failures. Status code 301 indicates the tests were aborted before completion; therefore, the reported results may be incomplete.

Table 6-2. General Self Test Results

CODE	DESCRIPTION
00	No self test
301	Self tests aborted

**Digital Tests****6-25.**

The digital tests (see Table 6-3) perform basic checks of the circuitry on the A13 Controller PCA.

Table 6-3. Digital Test Results

CODE	DESCRIPTION
302	Calibration/compensation memory checksum test failed
303	RAM test failed
304	EPROM test failed
305	Nonvolatile memory test failed
306	IEEE interface test failed

The calibration/compensation memory test verifies the CRC checksums of each calibration/compensation data segment in the battery-backed RAM (U8) and in the EEPROM (U9). If any of the tests fail, status code 302 is reported. See "Calibration/Compensation Memory Status" in Section 6B for further details.

## CIRCUIT DESCRIPTION, TROUBLESHOOTING, AND ALIGNMENT

The system RAM (U6 and U7) is tested at power-up by writing data to each memory location and verifying that the same data can be read back. The four program EPROMs (U2, U3, U4 and U5) are tested by verifying their checksums. The nonvolatile RAM is tested by verifying the checksum of each memory location.

Communication with the IEEE-488 interface IC is verified by writing data to the IEEE-488 talker/listener IC (U28), then reading it back.

### AM Tests

6-26.

The AM tests program normal and overmodulation conditions and then check the state of the ALC loop-level indicator. Table 6-4 lists the test conditions.

Table 6-6. Phase Modulation Test Conditions

CODE	ØM DEV	MOD FREQ	HIGH-RATE ØM	EXPECTED STATE OF FM LOOP
316	100 rad	1 kHz	Off	Locked
317	10 rad	20 kHz	On	Locked
RF Frequency = 640 MHz RF Amplitude = 0 dBm Mod Frequency = 1 kHz Internal ØM = On				

### FM Tests

6-27.

The FM tests program normal and overmodulation conditions, then check the state of the FM loop-lock indicator. The locked condition is expected in four of the FM bands and once with the Low-Rate FM mode enabled. The unlocked condition is expected when a very wide deviation is programmed at a low modulation rate. Table 6-5 lists the test conditions.

Table 6-5. FM Tests

CODE	FM DEV	MOD FREQ	LOW-RATE FM	EXPECTED STATE OF FM LOOP
310	100 kHz	1 kHz	Off	Locked
311	4 MHz	30 Hz	Off	Unlocked
312	4 MHz	63 Hz	Off	Locked
313	20 kHz	1 kHz	Off	Locked
314	10 kHz	1 kHz	Off	Locked
315	60 kHz	30 Hz	On	Locked
RF Frequency = 640 MHz RF Amplitude = 0 dBm Mod Frequency = 1 kHz Internal FM = On				

**ϕM Tests****6-28.**

The phase modulation tests verify that the FM loop remains locked when two valid phase modulation settings are programmed. The first test is performed at a high deviation. The second test is performed with the high-rate ϕM mode enabled. Table 6-6 lists the test conditions.

**Table 6-6. Phase Modulation Test Conditions**

CODE	ϕM DEV	MOD FREQ	HIGH-RATE ϕM	EXPECTED STATE OF FM LOOP
316	100 rad	1 kHz	Off	Locked
317	10 rad	20 kHz	On	Locked
RF Frequency = 640 MHz RF Amplitude = 0 dBm Mod Frequency = 1 kHz Internal ϕM = On				

**DC FM Test****6-29.**

The dc FM test (see Table 6-7) verifies the operation of the DC FM status indicator. This indicator reports the relative position of the dc FM dac setting to the corresponding ac FM control voltage. When the dc FM dac is set to full scale, the indicator should report that it is too high.

**Table 6-7. DC FM Tests**

CODE	DCFM DAC	EXPECTED STATE OF DCFM HI/LO INDICATOR
319	4095	High
RF Frequency = 640 MHz RF Amplitude = 0 dBm		

**Coarse Loop Tests****6-30.**

The first three Coarse Loop tests in Table 6-8 program a frequency in each of the three coarse loop vco bands with the normal steering dac value. The loop should remain locked. The fourth test in the table programs a valid frequency but the steering dac is set to zero. This should force the loop to unlock.

**Table 6-8. Coarse Loop Tests**

CODE	COARSE LOOP FREQUENCY	COARSE STEER DAC	EXPECTED STATE OF COARSE LOOP
320	640 MHz	Normal	Locked
321	768 MHz	Normal	Locked
322	896 MHz	Normal	Locked
323	640 MHz	0	Unlocked

**Subsynthesizer Tests**

**6-31.**

The first Subsynthesizer test in Table 6-9 programs a valid frequency near the center of the Subsynthesizer range and expects the Subsynthesizer to remain locked. The next two tests in the table force the Subsynthesizer to frequencies outside of its normal operating range with the expectation that it will unlock.

**Table 6-9. Subsynthesizer Tests**

CODE	RF FREQUENCY	SUBSYNTHESIZER FREQUENCY	EXPECTED STATE OF SUBSYNTHESIZER
324	804.000000 MHz	240 MHz	Locked
325	800.000000 MHz	120 MHz	Unlocked
326	807.999999 MHz	350 MHz	Unlocked

**Sum Loop Tests**

**6-32.**

The first four Sum Loop tests in Table 6-10 program a frequency in each of the four Sum Loop VCO bands with the normal steering dac value with the expectation the loop will remain locked. The fifth test in the table programs a valid frequency but the steering dac is set to zero. This should force the loop to unlock.

The next two tests program 4 MHz of FM deviation at a low and a high modulation rate and with the expectation that the sum loop will remain locked.

**Table 6-10. Sum Loop Tests**

CODE	FREQUENCY	SUM STEER DAC	INT FM	FM DEV	MOD FREQ	EXPECTED STATE OF SUM LOOP
327	550 MHz	Normal	Off	-	-	Locked
328	700 MHz	Normal	Off	-	-	Locked
329	830 MHz	Normal	Off	-	-	Locked
330	975 MHz	Normal	Off	-	-	Locked
331	550 MHz	0	Off	-	-	Unlocked
332	800 MHz	Normal	On	4 MHz	50 kHz	Locked
333	800 MHz	Normal	On	4 MHz	63 Hz	Locked

**RF OUTPUT Tests**

**6-33.**

The RF output tests (see Table 6-11) verify the presence of an RF signal at the output of the Attenuator/RPP assembly. The sensitivity of the RPP detection circuitry is increased so that it can be used as a RF signal detector. The first test programs a high RF level at a frequency in the fundamental frequency band with the expectation that the RPP indicator will trip. The second test programs a high RF level at a frequency in the HET frequency band with the expectation that the RPP indicator will trip. The third test programs a level below the detector threshold with the expectation that the indicator will not trip.

Table 6-11. RF Output Tests

CODE	RF FREQUENCY	AMPLITUDE	EXPECTED STATE OF RPP INDICATOR
334	800 MHz	+16 dBm	Tripped
335	1 MHz	+16 dBm	Tripped
336	800 MHz	+7 dBm	Not tripped

**Pulse Modulator Tests****6-34.**

The Pulse Modulator Tests (see Table 6-12) configure the RPP circuitry to its high sensitivity mode as in the RF output tests. The first test programs a high RF level and enables the internal pulse. The internal modulation oscillator sends a steady logic "low" to the pulse modulator; therefore, the pulse modulator will attenuate the RF output, and the RPP indicator will not trip. The second test configures the mod oscillator to send a steady logic high to the pulse modulator; therefore, the pulse modulator will not attenuate the RF output, and the RPP indicator will trip.

Table 6-12. Pulse Modulator Tests

CODE	RF FREQUENCY	AMPLITUDE	PULSE CONTROL LOGIC LEVEL	EXPECTED STATE OF RPP INDICATOR
337	800 MHz	+16 dBm	Low	Not tripped
338	800 MHz	+16 dBm	High	Tripped

**Filter Tests****6-35.**

The Filter Tests (see Table 6-13) verify the selection and operation of each of the output filter and divider sections. The first group of tests program a frequency within the band of interest and programs the correct filter and divider settings. The ALC loop-leveled indicator should report that the loop is leveled.

The next group of tests program filter settings that do not correspond with the programmed frequency. The ALC loop-leveled indicator should report that the loop is unlevelled.

The third group of tests program the frequency just inside the passband of each of the double band filters and expect the ALC loop-leveled indicator to report that the loop is leveled.

The fourth group of tests program a frequency at either end of the double band with all filters disabled and expect the ALC loop-leveled indicator to report that the loop is unlevelled.

**STATUS SIGNALS AND STATUS CODES****6-36.**

Table 6-14. lists the major hardware status signals monitored by the software and the corresponding front panel status code.

**CIRCUIT DESCRIPTION, TROUBLESHOOTING, AND ALIGNMENT**

**Table 6-13. 6082A Filter Tests**

CODE	FREQUENCY	FREQ BAND	EXPECTED STATE OF ALC LOOP
339	20 MHz	15 to 22 MHz	Leveled
340	30 MHz	22 to 32 MHz	Leveled
341	40 MHz	32 to 47 MHz	Leveled
342	60 MHz	47 to 64 MHz	Leveled
343	100 MHz	64 to 128 MHz	Leveled
344	150 MHz	128 to 180 MHz	Leveled
345	200 MHz	180 to 256 MHz	Leveled
346	300 MHz	256 to 350 MHz	Leveled
347	400 MHz	350 to 512 MHz	Leveled
348	550 MHz	512 to 625 MHz	Leveled
349	650 MHz	625 to 730 MHz	Leveled
350	800 MHz	730 to 1056 MHz	Leveled
351 - 354 are not performed on the 6082A			
355	500 MHz	256 to 350 MHz	Unleveled
356	1024 MHz	512 to 730 MHz	Unleveled
357	1250 MHz	1056 to 1250 MHz	Leveled
358	1250 MHz	1250 to 1450 MHz	Leveled
359	1450 MHz	1250 to 1450 MHz	Leveled
360	1450 MHz	1450 to 1750 MHz	Leveled
361	1750 MHz	1450 to 1750 MHz	Leveled
362	1750 MHz	1750 to 2112 MHz	Leveled
363	1056 MHz	X2 Band, All filters off	Unleveled
364	2112 MHz	X2 Band, All filters off	Unleveled
Amplitude = 15.0 dBm			

**Table 6-14. 6082 Status Signals and Codes**

ASSEMBLY	STATUS CODE	SIGNAL	DESCRIPTION
A7 Attenuator/RPP	240	RPTRPL	RPP tripped
A32 Premodulator	241	ALCUNLVL	ALC loop unleveled or AM overmodulation
A4 Subsynthesizer	242	SUBUNLKL	Subsynthesizer unlocked
A2 Coarse Loop	243	CORUNLKL	Coarse loop unlocked
A12 Sum Loop	244	SUMUNLKL	Sum loop unlocked
A12 Sum Loop	245	SUMUNLVL	Sum loop unleveled
A2 Coarse Loop	246	REFUNLKL	Reference loop unlocked
A14 FM loop	247	FMUNLKL	FM loop unlocked or FM overmodulation

**SOFTWARE DIAGNOSTIC FUNCTIONS****6-37.**

The instrument software includes built-in diagnostic functions to aid troubleshooting and alignment.

**Digital Control Latch Test****6-38.**

Special Function 903, the Latch Test, generates continuous activity on the data and address buses so the activity can be monitored with an oscilloscope.

When the test is initiated, the message "LAtch AA" is displayed, and the bit pattern 10101010 (Hexadecimal AA) is written continuously to each of the decoded module I/O latch positions. The data is written to each address in sequence so that the activity on the address bus is regular. Pressing the STEP  key changes the displayed message to "LAtch 55", and the bit pattern is changed to 01010101 (Hexadecimal 55). Pressing the STEP  key changes the pattern back to 10101010. Press any other key to exit.

**Instrument Diagnostic State****6-39.**

Special Function 909 programs the instrument to a predefined state used by several of the troubleshooting and alignment procedures. First, the instrument preset state (special function 01) is programmed to disable most special functions. Then, the diagnostic state is programmed immediately. The significant parameter settings of the diagnostic state are listed in Table 6-15.

Table 6-15. Parameter Settings of Diagnostic States

PARAMETER	SETTINGS
Frequency	300 MHz
Amplitude	-10.0 dBm
AM Depth	30.0 %
FM Deviation	5.00 kHz
Mod Frequency	1.00 kHz
All Modulation	Off

**Set Internal DACs****6-40.**

All internal dacs can be simultaneously forced to a predetermined setting for troubleshooting and alignment by special function. The settings are described in Table 6-16.

**NOTE**

*The Synthesizer DAC (U7) on the A6 Modulation Oscillator PCA cannot be set to mid scale with Special Function 942.*

Table 6-16. Set Internal DACs Special Functions

CODE	FUNCTION
941	Set all dac's to zero
942	Set all dac's to mid scale
943	Set all dac's to full scale

**Display Synthesizer Loop Frequencies**

**6-41.**

The sum loop, coarse loop, and Subsynthesizer frequencies for the programmed RF output frequency can be displayed by the Special Functions listed in Table 6-17.

**Table 6-17. Display Synthesizer Loop Frequencies Special Functions**

CODE	FUNCTION
945	Display Sum Loop frequency
946	Display Coarse Loop frequency
947	Display Subsynthesizer frequency

## Section 6A Power Supply

### POWER SUPPLY BLOCK DIAGRAM

6A-1.

Refer to the Power Supply Block Diagram, Figure 6A-1, to identify the major functional sections of the power supply and for help in following the power and current paths of the power supply.

### POWER SUPPLY CIRCUIT DESCRIPTION

6A-2.

Refer to the Power Supply schematic diagram in Section 10 while reading this description. The power supply provides all dc and ac power requirements for the Signal Generator. DC power is supplied to all system circuitry and operates the dc fan. AC power is used for filament heat for the front panel display.

The line voltage selector card, located in the case (rear panel) of the line fused receptacle/filter, accommodates the various line voltages that the instrument operates from. The card can be installed in any one of four configurations to allow selection of one of the following line voltages: 100, 110, 220, or 240V ac.

Line power passes through the line filter and fuse and is then routed to the primary winding of the power transformer. The transformer includes an additional safety device, which serves as a thermal shutoff to break the primary ac supply in case the transformer exceeds its safe operating temperature.

The secondary windings of the transformer are connected to a linear dc power supply assembly that provides the instrument with the supplies shown in Table 6A-1.

The front panel POWER pushbutton switches the instrument between the operate and standby modes. Note that the standby (STBY) mode, indicated by the illuminated yellow LED, does not remove power from the instrument. Two supplies continue to be active in the standby mode: the 23.4V supply and the display filament lines. Additionally, parts of the power supply, including the transformer secondary windings, rectifiers, and filter capacitors, are still energized.

Figure 6A-1 shows bridge rectifier configurations as well as the component designations for the various supplies. Rectifiers in the power supply are used in both a bridge and full-wave center-tapped configurations with capacitor input filters.

The +24V, +23.4V, -5V, 37V, and +30V supplies use conventional three-terminal IC regulators with internal current-limit and temperature protection.

POWER SUPPLY

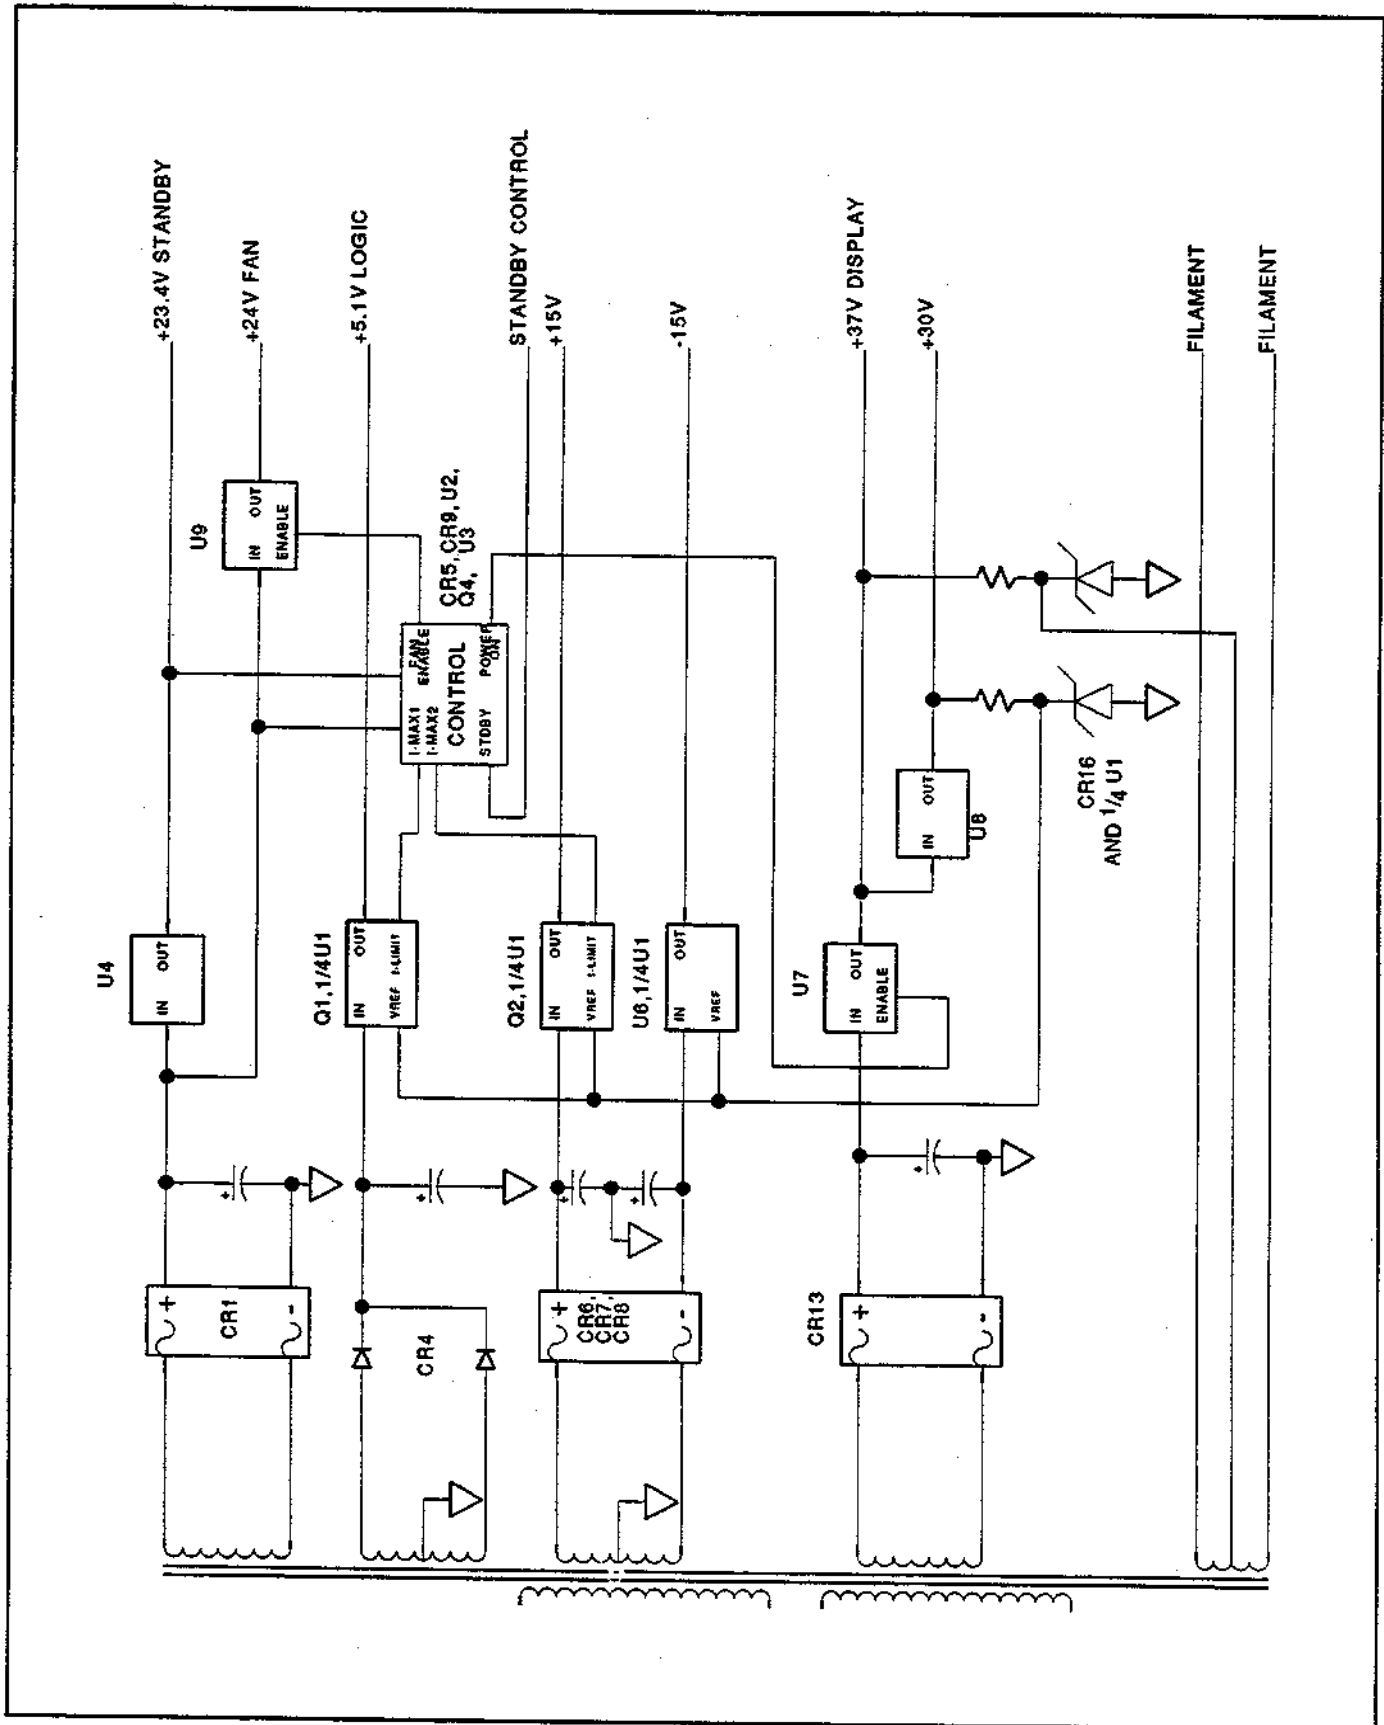

Figure 6A-1. Power Supply Block Diagram

Table 6A-1. Supplies Provided by Power Supply Assembly

VOLTAGE	SUPPLY
+24V dc	Fan and Attenuator
+23.4V dc	Oven and Front Panel (Standby Supply)
+5.1V dc	Logic
+15V dc	Positive Analog
-15V dc	Negative Analog
+37V dc	Front Panel Display
+30V dc	High Voltage Analog
6V ac	Display Filament Lines

The two highest power regulators, +5.1V and +15V are very low noise, low ripple design. They use a high gain, low noise amplifier U1, in a closed loop circuit with high current sense FET transistors Q1 and Q2.

Overcurrent protection is provided to both the +5.1V and +15V supplies via sense FET series-pass element's (Q1 and Q2) internal current mirror, in conjunction with the differential amplifiers (U2). When the load current set by R6 or R18 exceeds the preset limit, zener diodes CR5 or CR9 turn on, triggering the gate of SCR Q4. This sets pin 5 of comparator U3 below its threshold voltage, set by R19 and R22. This sets the adjust terminal of the 37V regulator to -1.3V and turns off the 37V supply. When the 37V supply is turned off, the +30V, +5V reference, the +5.1V, +15V, and -15V supplies are also turned off. The 24V fan supply is not turned off on this current limit. Q4 acts as a memory element that requires resetting after it is turned on. This can be done by turning off the front panel POWER switch.

The +5V reference is adjusted to 5.10V (at TP6) via the supply adjustment potentiometer R41. This adjustment sets up the +5.1V, +15V, and -15V supplies. These supplies track the +5V reference.

The -15V supply is a low-noise, low-ripple design that uses a high-gain, low-noise amplifier (U1) in a closed-loop circuit with a conventional three-terminal IC regulator U6. This circuit provides current limit and temperature protection.

Diodes CR12 and CR14 protect the +15V and -15V regulated supplies from reverse voltages. CR20 protects the +5.1V supply from both reverse voltages and overvoltages.

A +6.2V supply is developed from the +37V supply through resistor R34 and zener diode CR15. The +6.2V supply is then applied to the center tap of the 6V ac filament supply. This provides the necessary grid bias for the front panel displays.

A -5V local supply (U5) is generated on the Power Supply PCA. This supply provides negative voltage to U1 and a -1.3V shut off voltage for U7, U9, and U3. Triac Q3 is a voltage surge protector that protects against line voltage surges as well as overvoltage in case the line power selector card is set incorrectly. When the voltage across the +5.1V secondary winding of the transformer is excessive, CR2 or CR3 conducts current and turns on the gate of Q3. When Q3 conducts, it shorts the secondary winding of the transformer and causes the power line fuse to blow.

To reduce power supply ripple, the common reference terminals of the voltage regulators are connected to an external ground point (P2) on the module section. To prevent damage to the power supply circuitry, all GND lines and the GND SENSE line are grounded to the chassis.

## POWER SUPPLY TROUBLESHOOTING

6A-3.

### WARNING

**TO AVOID ELECTRIC SHOCK, USE EXTREME CAUTION WHEN TROUBLESHOOTING THE POWER SUPPLY. TURNING OFF THE FRONT PANEL POWER SWITCH DOES NOT REMOVE POWER FROM THE PCA. SOME POWER SUPPLY CIRCUITS REMAIN ENERGIZED AS LONG AS THE POWER CORD IS PLUGGED INTO AC LINE POWER.**

To access the power supply, remove the rear panel from the instrument and remove the Power Supply PCA from its bracket.

Connect the GND lines and the GND SENSE lines to the controller connector (J4 pins 5,6,7) to reduce ground loops. Connect load resistors that correspond to the load current indicated on the power supply schematic to each of the voltage supply lines.

### CAUTION

**WHEN OPERATING THE POWER SUPPLY FOR LONGER THAN 5 MINUTES AT A TIME, MAKE SURE THE FAN IS AIMED AT THE POWER DISSIPATORS. FAILURE TO PROVIDE ADEQUATE AIR FLOW MAY DAMAGE POWER SUPPLY COMPONENTS.**

## Troubleshooting Procedure

6A-4.

Troubleshoot the power supply as described in the following procedure:

1. Set the power supply to the standby mode (front panel yellow LED on).
2. Verify that the two standby supplies are operating within their specified voltage ranges as listed below:
  - TP2, 23.4V supply = 24V ( $\pm 5\%$ )
  - TP14, -5V supply = -5V ( $\pm 5\%$ )

Next verify all other supplies are turned off.

- TP18, 24V supply = 0V ( $\pm 0.1V$ )
- TP6, +5.1V supply = 0V ( $\pm 0.1V$ )
- TP11, +15V supply = 0V ( $\pm 0.1V$ )
- TP16, -15V supply = 0V ( $\pm 0.1V$ )
- TP20, 37V supply = 0V ( $\pm 0.1V$ )
- TP21, 30V supply = 0V ( $\pm 0.1V$ )
- TP15, +5V reference = 0V ( $\pm 0.1V$ )

- a. If either of the 23.4V or -5V supplies are not at the specified voltage, check the unregulated supplies (TP13 and TP1, respectively).

- b. If some of the supplies that are supposed to be off are partially or fully turned on, check the 37V supply (TP20) voltage.
  - c. If the 37V supply is partially or fully on, check the standby switching circuit and the comparator operation (U3, Q5, R52).
3. Switch the power supply on by connecting the STANDBY line (J6 pin 4) to GND (J6 pin 7,8).
  4. Verify that all supplies are operating and are within the following specified levels:
    - TP18, 24V supply = 24V ( $\pm 5\%$ )
    - TP2, 23.4V supply = 24V ( $\pm 5\%$ )
    - TP6, +5.1V supply = 5.1V ( $\pm 2\%$ )
    - TP11, +15V supply = 15V ( $\pm 4\%$ )
    - TP16, -15V supply = -15V ( $\pm 4\%$ )
    - TP14, -5V supply = -5V ( $\pm 5\%$ )
    - TP20, 37V supply = 37V ( $\pm 5\%$ )
    - TP21, 30V supply = 30V ( $\pm 5\%$ )
    - TP15, +5V reference = 5V ( $\pm 3\%$ )
    - a. If all supplies are at the appropriate voltages when in standby, but are not at the appropriate voltages when the power supply is turned on, the shutoff circuit may have failed caused a voltage failure. Verify a second time that the standby supplies are 24V  $\pm 5\%$  and -5V  $\pm 5\%$ .
    - b. If the 24V fan supply is on and the rest of the supplies (except for 23.4 and -5V) are off, check the current limit circuitry (U2, CR5, CR9, Q4). A short of either the +15 or the +5.1V line could cause the current limit to trip and turn all non-standby supplies off (except the fan supply). In this case, verify that the voltage at TP22 is less than 1V, which indicates a current limit trip. To recover from a current limit shutoff, turn the power supply to standby operation (power switch off) for at least 5 seconds.
    - c. If only the +5V reference, +5.1V, +15V, and the -15V supplies are in error, check the +5V reference circuitry, since it is likely that the fault is with the reference supply circuitry, U1 and CR16.

## POWER SUPPLY ADJUSTMENT PROCEDURE

6A-5.

A single potentiometer (R41) adjusts the voltage output of the three discrete supplies: the +5.1, +15, and -15V. To perform these adjustments, connect a voltmeter to the +5.1V supply (TP6), and adjust R41 for 5.1V ( $\pm 0.05V$ ). Once the +5.1V supply is adjusted, both the +15 and the -15V supplies should operate at 15V  $\pm 0.2V$ .

## Section 6B Digital Controller

### DIGITAL CONTROLLER BLOCK DIAGRAM

6B-1.

The A13 Controller PCA, under the direction of the instrument software, handles the data interface between the front panel, remote interface, and 6082A functions. The controller is located in a top side compartment of the lower module section.

The controller consists of the following functional groups:

- Microprocessor
- Memory
- Memory Control
- Front Panel Interface
- IEEE-488 Interface
- Attenuator Control Interface
- Module I/O Interface
- Status and Control Latches

Refer to Figure 6B-1 to identify the major sections and trace signal paths.

### DIGITAL CONTROLLER CIRCUIT DESCRIPTION (A13)

6B-2.

#### Microprocessor

6B-3.

The software is executed on a 68HC000 16-bit microprocessor. The 8-MHz digital system clock signal is generated by an oscillator made up of gates from U18 and crystal Y1.

Supply voltage monitor TL7705A (U13) generates the active low reset signal to the 68HC000. The reset signal is generated on power-up or when the +5V supply drops below +4.5V. The reset signal remains low for 200 ms.

#### Memory

6B-4.

The program instructions and constant data are stored in four 128-KB EPROMs, U2-U5. The stack and program variables are stored in two 32-KB static RAMs U6 and U7. Nonvolatile instrument state memory and one half of the redundant calibration/compensation memory are contained in battery-backed CMOS RAM U8. The other half of the redundant calibration/compensation memory is contained in EEPROM U9.

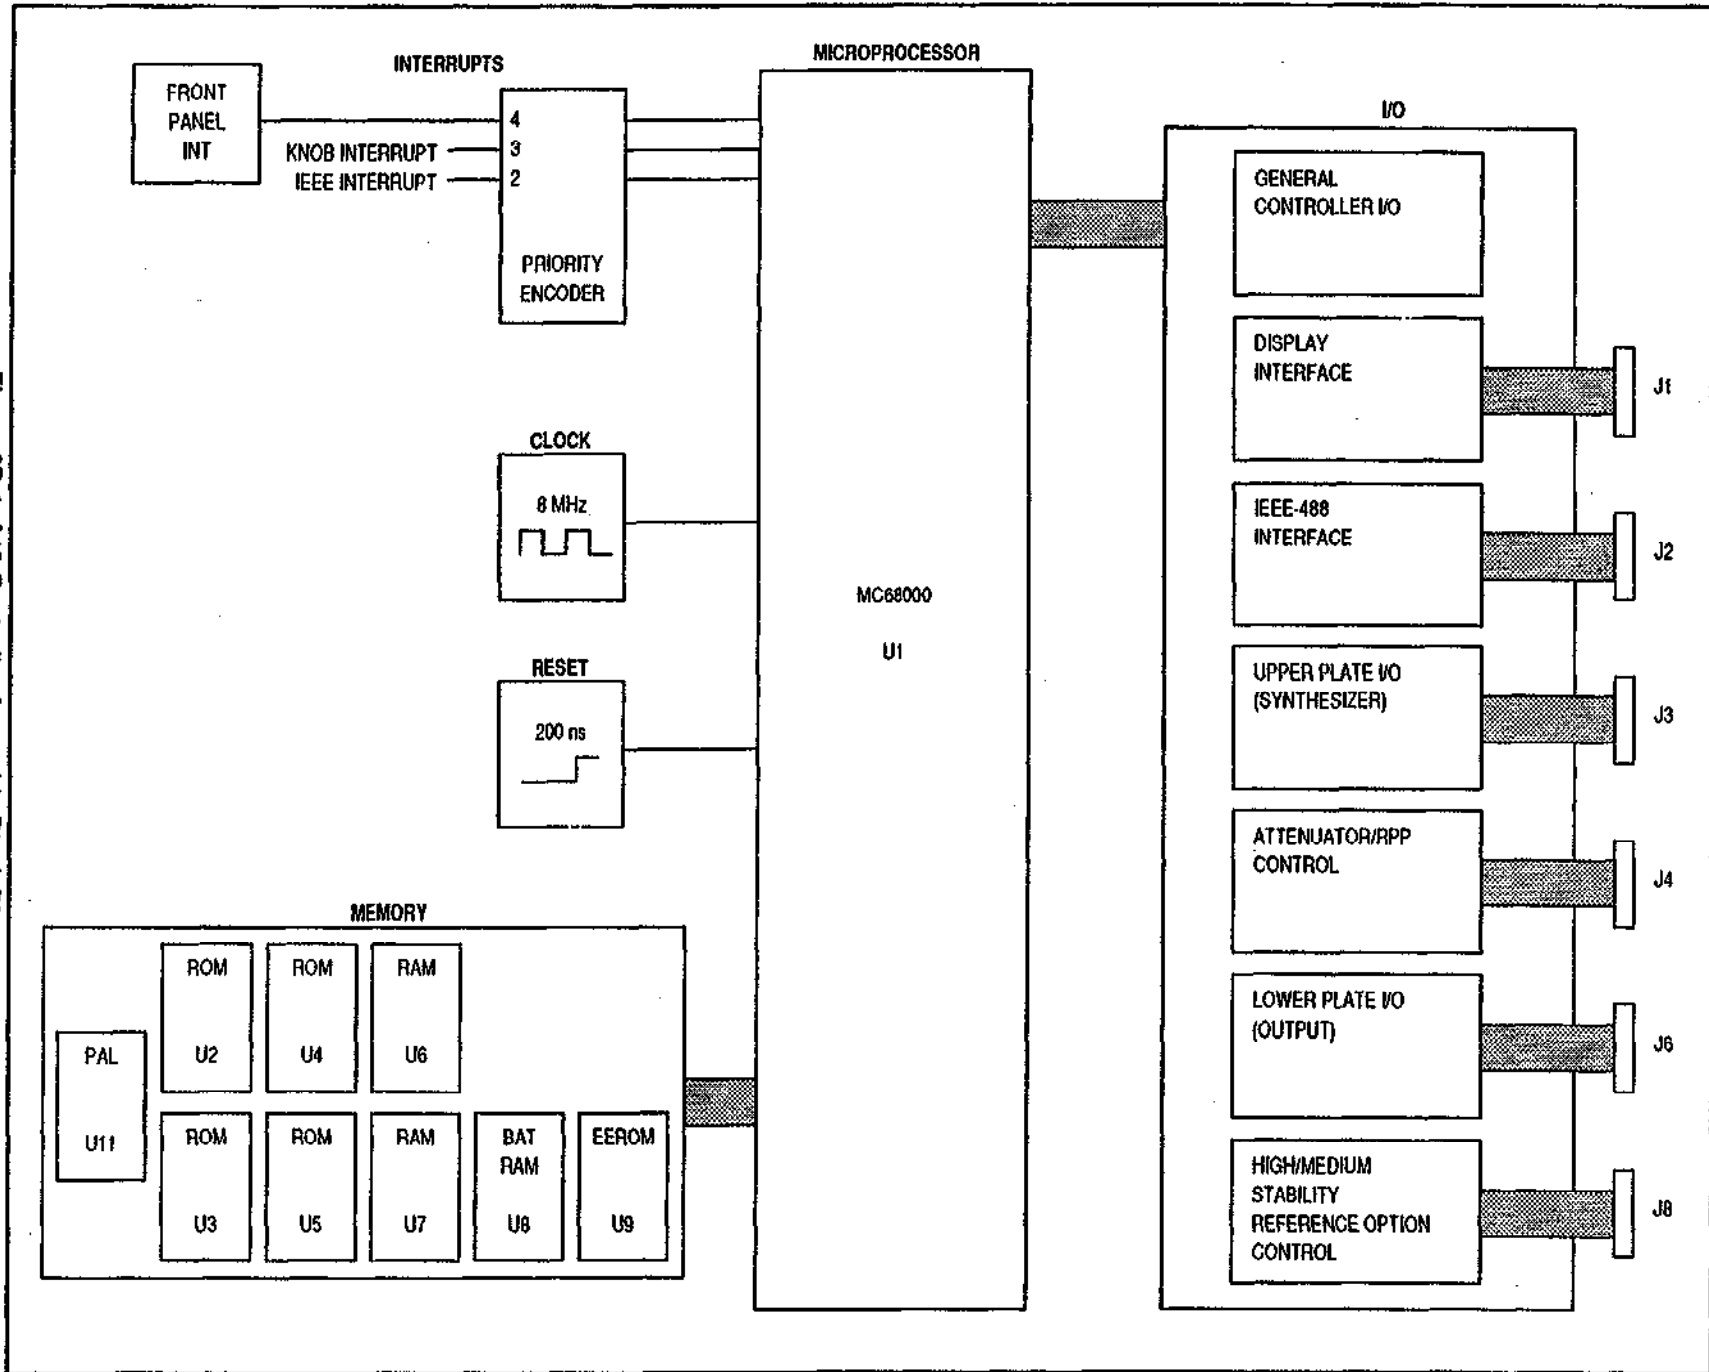

Figure 6B-1. A13 Controller Assembly Block Diagram

The rear panel CAL/COMP switch protects the calibration/compensation memory from accidental destruction.

### Memory Control

**6B-5.**

Decoder PAL U11 decodes the memory selects and contains additional write-protection logic for calibration/compensation memory and the instrument states stored in the battery-backed RAM. Timing PAL U15 adds one wait state to each memory read or write cycle.

Individual upper-byte and lower-byte read and write enable signals are generated from 68HC000 control signals R/W, UDS, and LDS by U22. Signals RDU and RDL are read enables for the upper-byte and lower-byte respectively. Signals WRU and WRL are write enables for the upper-byte and lower-byte respectively.

### Front Panel Interface

**6B-6.**

Data is transferred to and from the front panel circuitry through tri-state bidirectional data buffer U31. The corresponding address signals are transferred through tri-state buffer U32. These buffers are active when a front panel latch is addressed and the buffer control signal from U43 is low. Otherwise, the buffer is in the high-impedance state. To reduce RF emissions from the Signal Generator, low-pass filters and bypass capacitors are used on all data and select signals to the front panel.

The front panel interrupt rate is determined by the binary dividers U14 and U20. The system clock is divided by 8192 to generate a front panel interrupt every 540 microseconds.

### IEEE-488 Interface

**6B-7.**

All IEEE-488 communications are handled by U28, an NEC  $\mu$ PD7210 talker/listener IC. The 7210 is connected directly to the system address and data bus and communicates with the microprocessor as a memory mapped I/O device.

The active low interrupt signal IEINTL is connected to the level two interrupt on the microprocessor. Tri-state bus drivers U29 and U30 interface the 7210 directly to the IEEE-488 bus.

### Attenuator Control Interface

**6B-8.**

The attenuator control signals are latched by U39. Darlington driver U40 provides the level shifting necessary to control the A7 Relay Driver/RPP PCA.

### Module I/O Interface

**6B-9.**

Control data is transferred to the RF circuitry through two byte-wide unidirectional data buses. Data is transferred to the upper module through J3 and to the lower module through J6.

Select lines BSEL0L, BSEL1L, and BSEL5L, and address lines SAB2, SAB1, and SAB0 are decoded into individual latch enables for the upper module on the A4 Subsynthesizer PCA. Tri-state buffers U24 and U33 provide drive current when active and allow these signals to float when inactive.

Select lines BSEL2L, BSEL3L, and BSEL4L and address lines BAB2, BAB1, and BAB0 are decoded into individual latch enables for the lower module on the A33 Modulation Control PCA. Tri-state buffers U25 and U27 provide drive current when active and allow these signals to float when inactive.

Timing PAL U15 adds additional wait states to each module I/O write cycle to ensure that adequate setup and hold times are provided for every IC on the bus.

### Status and Control Latches

6B-10.

Input buffers U35, U36, U37, and U45 read the fault detector signals, hardware status signals, the option status signals, and the status of the REF INT/EXT and CAL/COMP switches. Control and buffer enable data is latched by output latches U34 and U38.

## DIGITAL CONTROLLER TROUBLESHOOTING

6B-11.

A properly operating front panel indicates that most of the controller and display circuitry is functional. Therefore, the most obvious symptom of failure in the A13 Controller PCA is a blank front panel. If the front panel is totally blank or unresponsive to keystrokes, refer to Section 6A, Power Supply, and verify that all assemblies are receiving the correct voltages. If all voltages are correct, refer to "Microprocessor Kernel" further on in this section.

If the front panel is operating correctly but the RF output is incorrect, try to determine if the fault is on the controller or on an RF circuit board by programming various functions and checking for status codes.

If the symptoms indicate a digital or control failure, the following paragraphs may help isolate the fault to a particular functional circuit. Refer to the A13 Controller PCA schematic diagram in Section 10.

### RF Control

6B-12.

Communication with the RF circuitry in the upper and lower modules is through connectors J3 and J6 respectively. The RF data and control signals to both modules are buffered by tri-state drivers that are active only while data is being transferred and are in the high-impedance state at all other times.

Special Function 903, the latch test, generates continuous activity on the data and address buses so that the activity can be monitored with an oscilloscope. The latch test is described under "Software Diagnostic Functions" in Section 6.

Enter Special Function 903 to initiate the latch test. Use an oscilloscope to inspect the chip select signals at the inputs and outputs of buffers U24 and U25. The first symptom to look for is inactive signals or invalid logic states. If there are no chip select signals present at the inputs of U23, refer to "Address Decoding" later in this section.

If all of the chip select signals are operating correctly, connect an oscilloscope probe to the signal BSEL0L and use the high-to-low transition of the signal to trigger the oscilloscope. Use another probe to inspect the data and address signals buffered by U24, U25, U27, and U33 during the low period of BSEL0L. Look for inactive signals and invalid logic states. Also compare the buffer inputs to their outputs. Press the STEP  key, then the STEP  key to toggle each of the data signals. In addition, make sure that the buffer control signals are low (active).

If the signals pass the above tests, check the data and address signals at any suspicious latch or dac on the suspect RF circuit board. If a dac problem is suspected, use special functions 941, 942, and 943 to set all dacs to zero, half scale, and full scale respectively.

### Microprocessor Kernel

**6B-13.**

Microprocessor-related problems are difficult to troubleshoot because of the volume of activity at any given time. However, you can systematically verify independent circuit functions and isolate some of the most obvious problems. Read the following paragraphs and check the related circuitry.

### Clock

**6B-14.**

Connect an oscilloscope probe to the clock oscillator output (TP4). There should be a symmetrical 8-MHz square wave with adequate logic levels. If the signal appears abnormal, check the input signal at U18 pin 3 to determine if there is a problem with the oscillator circuit or the ICs connected to the clock output. The square wave should be an inverted version of the same 8-MHz square wave on U18 pin 4 (it may be slightly distorted due to its loading).

### Power-On Reset

**6B-15.**

Connect an oscilloscope probe to the RESET input, U1 pin 18. The signal should generate a low-to-high transition on power-up and remain high during normal operation. Turning the power off and on generates an active low reset pulse approximately 200 ms wide.

If the reset pulse to U1 appears abnormal, compare it to the reset output of the power supply monitor IC, U13 pin 5. If this reset pulse is abnormal, suspect problems with U13, and all ICs connected to the RESETL and RESETH signals.

Also check the HALT input, U1 pin 17; it should look like the RESET input on U1 pin 18.

### Unused Microprocessor Inputs

**6B-16.**

Input signals to U1, BR (pin 13) and BGACK (pin 12) should both be high. If either of these signals is not high, correct the fault before continuing.

### Bus Error

**6B-17.**

The bus error input BERR, U1 pin 22, notifies the microprocessor when a memory cycle cannot be completed as a result of a hardware fault. Normally, the BERR signal should always remain high.

If the BERR signal goes low, verify that U14 pin 1 is clocked by an 800-kHz signal with a 60/40 duty cycle. Also verify that U14 pin 2 is receiving continuous activity from the address strobe signal (AS).

### Interrupts

**6B-18.**

The front panel edit knob interrupt is generated on the A1 Display PCA when the knob is turned. The interrupt signal from the Display PCA connects to U12 pin 13. If the signal is low when the knob is in the rest position, refer to "Edit Knob Interface" further on in this section.

Under normal operation, a front panel interrupt is generated every 540 us at U21 pin 6. Verify that the divided outputs from U14 and U20 are correct and that a reset signal at U21 pin 1 is generated after each interrupt.

Verify that the IEEE-488 Interface interrupt signal, IEINTL (on pin 12 of U12) is in the inactive (high) state. If IEINTL is active, make sure the microprocessor kernel and buses are operating correctly, since the software must be operating before the IEEE interrupt can be initialized properly. If these are correct, troubleshoot communications with the IEEE-488 interface IC using the diagnostic tests under the heading "I/O Diagnostic Tests" further on in this section.

### Microprocessor Bus

**6B-19.**

The dynamic nature of the microprocessor bus makes it difficult to verify the data transmitted at any given time. However, most common bus faults show recognizable symptoms and can be found with the aid of the address bus diagnostic test.

To initiate the bus diagnostic test, turn off the instrument power and set DIP switches 2, 3, and 4 of S1 to the ON position. Remove U11 from its socket to disable all memory and I/O chip selects, then turn the power on. This test generates predictable activity on the control signals and the address bus.

Look at the bus control signals (AS, R/W, UDS, LDS) with an oscilloscope. Suspect inactive signals or signals that enter invalid logic states. Also compare the inputs and outputs of gated signals.

All the address bus signals should have square waves of varying frequencies. The least significant signal (A1) has the highest frequency, and successively higher order signals have a frequency half that of the previous line. Note that there are small glitches on all of the address signals during the low cycle. These are normal and are not really glitches. The address lines are momentarily tri-stated between bus cycles, and the pull-up resistors pull the signals only part way of the up before the next bus cycle begins.

If the microprocessor bus test does not function as described, suspect the microprocessor kernel and the data bus. Check for data lines shorted together or shorted to the power supply. Also look for ICs that may be driving the data bus.

If the control and address signals appear normal, turn the power off and set the DIP switches to the OFF position and install U11.

### Address Decoder

**6B-20.**

Several levels of address decoding are used to select the memory and I/O devices. Figure 6B-2 shows the levels of decoding.

Decoder PAL U11 generates the major memory segment selects. Verify that all of its address and control inputs are working properly. The signal CMWRL is the write-protection signal for the calibration/compensation memory. Signal CMWRL is connected directly to the rear panel CAL|COMP switch. Signals NVWR and COMPWR are software controlled write-protection signals for the nonvolatile memory and the calibration/compensation memory, respectively.

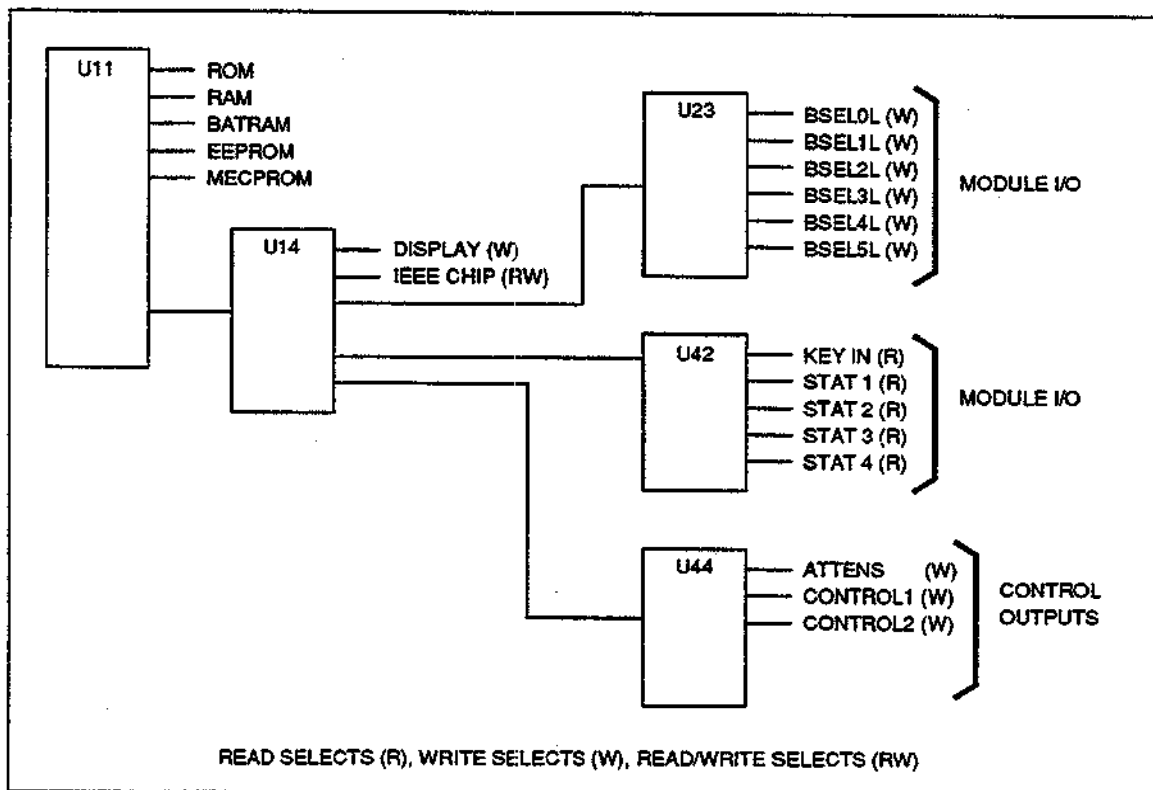

Figure 6B-2. Address Decoding

A chip select for the I/O circuitry is also generated by U11. Two additional levels of decoding generate the individual device selects. If U11 is operating correctly but the decoded chip select is not properly generated, proceed to the following diagnostic tests and perform whichever test is appropriate for the symptoms displayed.

### I/O Diagnostic Tests

### 6B-21.

Initiate a diagnostic routine that continuously writes the data byte 10101010 (binary) to each decoded I/O write location (labeled W or RW in Figure 6B-2). Momentarily ground TP1 on the controller if the data write-select lines to the display latches, the IEEE-488 talker/listener IC (U28), the module I/O control circuitry, or the control outputs are not generated properly. Momentarily grounding TP2 performs the same action but writes the data byte 01010101 (binary) instead.

If the data read selects to IEEE-488 talker/listener IC U28 or the status input buffers are not generated properly, momentarily ground TP3. This initiates a diagnostic routine that continuously reads data from each decoded read position (labeled R or RW in Figure 6B-2). Cycle the instrument power to terminate this diagnostic function.

These diagnostic tests write the data bytes very fast to more easily trigger an oscilloscope. Inspect the various I/O select signals and their relationship to the data and address signals. Normal software activity is halted so instrument power must be cycled to terminate the test.

The display should show an unusual combination of digits and segments since it is displaying an alternating bit pattern rather than the normal display data. Although the module I/O selects are generated by the tests, it may be easier to test the module I/O circuitry using the latch test once the microprocessor circuitry is fully functional.

**CALIBRATION/COMPENSATION MEMORY****6B-22.**

The integrity of the calibration/compensation data is vital to the performance of the instrument. The use of redundant data storage allows the system to recover even if some of the data has been corrupted.

There are 11 calibration/compensation data segments:

1. Attenuator
2. Coarse Loop Compensation
3. Coarse Loop Steering
4. Output
5. Subsynthesizer
6. Sum Loop Compensation
7. Sum Loop steering
8. AM Calibration
9. FM Calibration
10. RF Level Calibration
11. Reference Oscillator calibration.

Two copies of each data segment are maintained in two separate ICs on the Controller PCA. One copy is stored in EEPROM U9, and the other copy is stored in battery-backed RAM U8. If the power fails while either version is being updated, the other is still valid.

**Calibration/Compensation Memory Status****6B-23.**

Whenever the self-tests are performed, the checksums are verified for each data segment in EEPROM U9 and in battery-backed RAM U8. In addition, each checksum is compared to the corresponding checksum in the redundant data block. If one checksum is valid and the other is invalid, the valid copy is used. If both copies have invalid checksums, overrange/uncal status code 250 is set, and the STATUS annunciator flashes.

If any of the checksums fail, self-test status code 302 is reported. Special function 04 displays a list of codes that specify which checksums failed. The list can be scrolled by pressing the **STATUS** key. If all checksums are valid, the code 00 is displayed. Refer to Appendix E for a complete list of the checksum status codes.

The most likely failure mode would be a defective EEPROM or battery-backed RAM that would show failures of all the checksum error codes for that IC. Replace the defective IC, and refer to "Repairing Calibration/Compensation Memory Checksum Errors" later in this section.

In addition to checksum error codes, there are codes that indicate the checksums are valid, but a byte-by-byte comparison of the data segments reveals that they are different. This unusual condition is likely to occur only if one of the two calibration/compensation memory ICs have been swapped between controller boards. Although this situation rarely occurs, it is important to detect the condition so that corrective action can be taken. The data comparison codes are included with the checksum status codes in Appendix E.

**Repairing Calibration/Compensation Memory Checksum Errors 6B-24.**

Special Function 907 attempts to repair all invalid data segments reported by the calibration/compensation memory status command. Special Function 907 can be used to repair an error in an individual data segment or to initialize a new EEPROM or battery-backed RAM following the replacement of a defective part.

**NOTE**

*The rear panel CAL|COMP switch must be set to the "1" position before performing Special Function 907.*

If the checksums in both ICs are valid for a given data segment, no transfers are performed. However, if one checksum is valid and the other is invalid, the message "—Sto—" is displayed, and the good data is copied over the bad data. If both checksums are bad, no transfers can be performed. Each redundant data segment pair is checked and updated individually.

This also resolves the situation where a segment in EEPROM and in the battery-backed RAM both have valid checksums but contain different data. The EEPROM data segment is always copied to battery-backed RAM in this situation.

After all transfers are complete, the checksums are verified again and any remaining failures are reported.

**Calibration/Compensation Memory Origin Status 6B-25.**

Data in the calibration/compensation memory can be generated by:

- The Fluke factory
- The Module Exchange Center (MEC)
- You (by performing the calibration or compensation procedures)

The calibration/compensation data origin code specifies how the particular data segment was generated. A segment's data origin may have a bearing on future actions, so it is desirable to know how each was generated. Refer to Section 7, Compensation Procedures.

Special Function 05 displays the data origin codes. All data segments generated by the Fluke factory display origin code 00. Any data segments generated other ways display the corresponding status code. When there are more than four codes, scroll the list by pressing the **STATUS** key. Refer to Appendix F for a complete list of origin codes.

**FRONT PANEL CIRCUIT DESCRIPTION 6B-26.**

The front panel section, mounted in a sheet metal housing, consists of the A1 Display PCA, a switch circuit board, elastomeric switches, and the edit knob. The front panel section also includes the display lens, the AM INPUT connector, the FM/φM INPUT connector, and the PULSE INPUT connector.

All front panel control keys, except the POWER on/off button, consist of an elastomeric membrane sandwiched between the switch circuit board and the front panel sheet metal housing. The switch circuit board consists of an 8-by-8 matrix of open switch contact pads. When a key is pressed, a conductive pad on the back of the elastomeric membrane connects a set of contact pads. The software senses which row and column of the matrix is connected when a key is pressed. The two opto-interrupter ICs for the edit knob are the only active components mounted on the Switch PCA.

### Display PCA

6B-27.

The A1 Display PCA provides a readout of the programmed modulation, frequency, amplitude parameters, and status information. (Refer to its schematic in Section 10.) Displayed information and the bright digit are controlled by the A13 Controller PCA under the direction of the instrument software. The display is made up of two vacuum-fluorescent displays and their associated control circuitry. The two displays are refreshed as four groups of nine display fields (usually a digit) each. The four groups share the digit (grid) strobes but have individual segment (anode) strobes.

### Data Communications

6B-28.

Display data is sent through a byte-wide bidirectional data bus from the Controller PCA and is latched by U1 through U5, and U19. The front panel latch select signals DIG1L, DIG2L, SEG1L, SEG2L, SEG3L, and SEG9L, which are then decoded by U20. These latch select signals determine which latch receives the data. Level-shifting buffer drivers U6 through U10 interface the latches directly to the +37V grids and anodes of the vacuum-fluorescent displays.

### Display Filament Voltage

6B-29.

The 6.0V ac filament voltage for the display is derived from a center-tapped winding on the Power Supply PCA transformer (T1). The ac filament voltage is biased at +6.2V above ground by circuitry on the A14 Power Supply PCA to provide a cutoff potential for the displays.

### Bright-Digit Effect

6B-30.

The bright-digit effect is achieved by providing three extra refresh cycles (strobes) to the specified digit. Grid current-limiting resistor R3 ensures uniform digit brightness by controlling electron depletion from the display cathode filaments.

### Switchboard interface

6B-31.

The digit strobe data latched by U1 is buffered by open-drain inverters U13 and U15 and strobes the front panel switch matrix. The switch columns are strobed in unison with the display fields. The switch matrix status is read by tri-state buffer U14.

### Remote Footswitch (AUX Connector)

6B-32.

The inputs of the rear panel AUX connector accept remotely generated sequence up, sequence down, and bright-digit field (frequency or amplitude) commands. The requests are generated by momentarily grounding the desired signal. The pinout of this connector is provided in Appendix I.

The rear panel control inputs are static due to electromagnetic emission considerations. Gates in U12, U13, U15, and U16 convert the static rear panel inputs into strobed key requests. The software services these key requests in the same manner as the other strobed keys.

**Edit Knob Interface****6B-33.**

The edit knob interface circuitry receives two input signals (WINDOWL and TRIGGERL) from the opto-interrupters on the A19 Switch PCA.

If the trigger signal makes a high-to-low transition while the window signal is low, the software generates an edit-up request. The software transmits this information to the Controller PCA by setting the knob interrupt signal KNOBINTL low and the knob direction signal KNOBUP high.

If the trigger signal makes a low-to-high transition while the window signal is low, the software generates an edit-down request. The software transmits this information to the Controller PCA by setting the knob interrupt signal KNOBINTL low and the knob direction signal KNOBUP low.

The trigger signal is ignored when the window signal is high.

After servicing the interrupt and reading the directional information, the controller resets the knob circuitry by toggling the reset signal KNOBRSTL.

**Display Blanking****6B-34.**

Monostable U11 and NOR gate U12 clear the display when new field or segment strobes are not received. This protects the display if the microprocessor stops refreshing.

**Operate/Standby Selection****6B-35.**

The front panel POWER switch selects the operate or standby modes. The switch is closed in the standby position, which sets the STANDBY signal high and illuminates LED CR1. The switch is open in the operate position, which pulls the STANDBY signal low, and turns off LED CR1.

**FRONT PANEL TROUBLESHOOTING****6B-36.**

If the display shows signs of activity but has missing or bright digits or segments, the problem is most likely one of the data latches or drivers on the A1 Display PCA. If the display is blank and the controller is operational, check the power supplies (refer to Section 6A, Power Supply).

Use the I/O diagnostic tests described in the A13 Controller troubleshooting text to continuously write data to the display latches. Verify that the correct data is written to each latch and is present at the outputs of the display drivers. The display blanking output of U11 pin 13 should remain high while the data is written.

As the edit knob is rotated, the window and trigger signals should generate transitions on the input signals to U18 resulting in an interrupt at U12 pin 12. If the signals do not change as the knob is turned, suspect the opto-interrupters on the A19 switch PCA or the interconnection with the Switch PCA.

Two special-function service tests are available to test the front panel indicators and keys. Special function 901 checks the front panel displays by lighting all segments. Exit the test by pressing any key.

## DIGITAL CONTROLLER

Special function 902 initiates the key check. As each key is pressed, its identifier code is displayed in the center of the FREQUENCY display field. The key identifier codes are assigned in order from top to bottom and from left to right. This test is exited by a clear entry.

## Section 6C

# Frequency Synthesis

### FREQUENCY FAULT TREE

6C-1.

Refer to Figure 6C-1, Frequency Synthesis Fault Tree, when troubleshooting frequency-related problems.

### SUBSYNTHESIZER BLOCK DIAGRAM

6C-2.

The Subsynthesizer Block Diagram (Figure 6C-2) identifies the major functional blocks and signal paths of the Subsynthesizer.

### A4 SUBSYNTHESIZER CIRCUIT DESCRIPTION

6C-3.

The A4 Subsynthesizer PCA, in conjunction with the A3 Subsynthesizer VCO PCA generates a 16- to 32-MHz signal in 2-Hz steps. The Subsynthesizer PCA also distributes power, control lines, and programmable dc voltages to the A2 Coarse Loop PCA. Status lines from the Coarse Loop PCA to the A13 Controller PCA are also routed through the Subsynthesizer PCA.

The Subsynthesizer phase-locked loop (PLL) is a fractional divider PLL with a single-sideband (SSB) mixer in the feedback path. The PLL oscillator is located on the A3 Subsynthesizer VCO PCA and operates at a frequency of 160 to 320 MHz. A 10/1 divider on the VCO PCA produces the 16- to 32-MHz signal.

The key signals to the PLL are the 1-MHz reference signal from the 40 MHz reference circuit, the 160- to 320-MHz signal from the vco, and the 10- to 20-kHz signal from the low order digit generator circuit. The fractional division technique provides provides 10 kHz frequency resolution at the vco frequency (160 to 320 MHz).

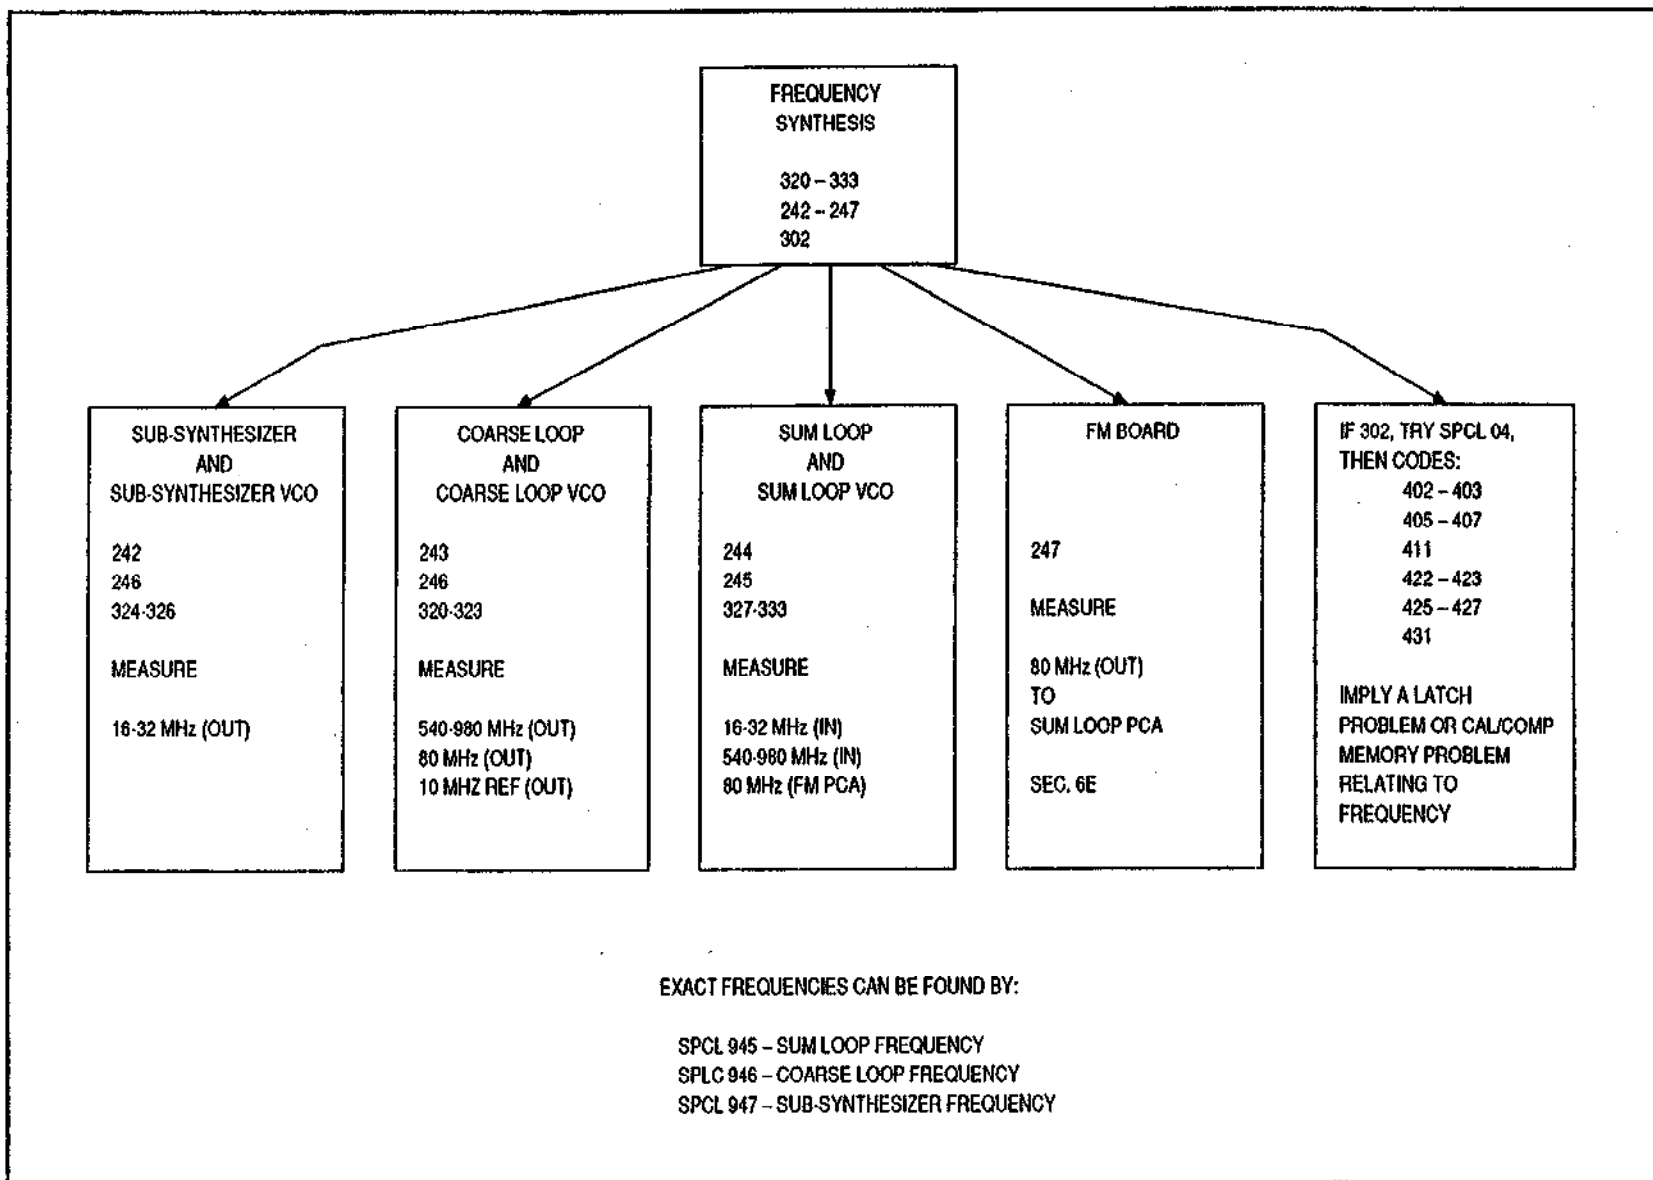

### Single-Sideband Mixer

6C-4.

The SSB mixer, in conjunction with the low order digit generator provides an additional 20-Hz resolution at the vco frequency.

The vco frequency of 160 to 320 MHz is input to J7 (refer to the A4 Subsynthesizer PCA schematic in Section 10) and filtered by C140 through C142, and L70 and L71. Then it is attenuated by R69 through R71 and amplified by U50. Resistors R101 through R103 attenuate the signal again and send it to be amplified by U51. At this point the signal is connected to U52, a quadrature (90-degree phase difference) 3-dB coupler.

Figure 6C-1. Frequency Synthesis Fault Tree

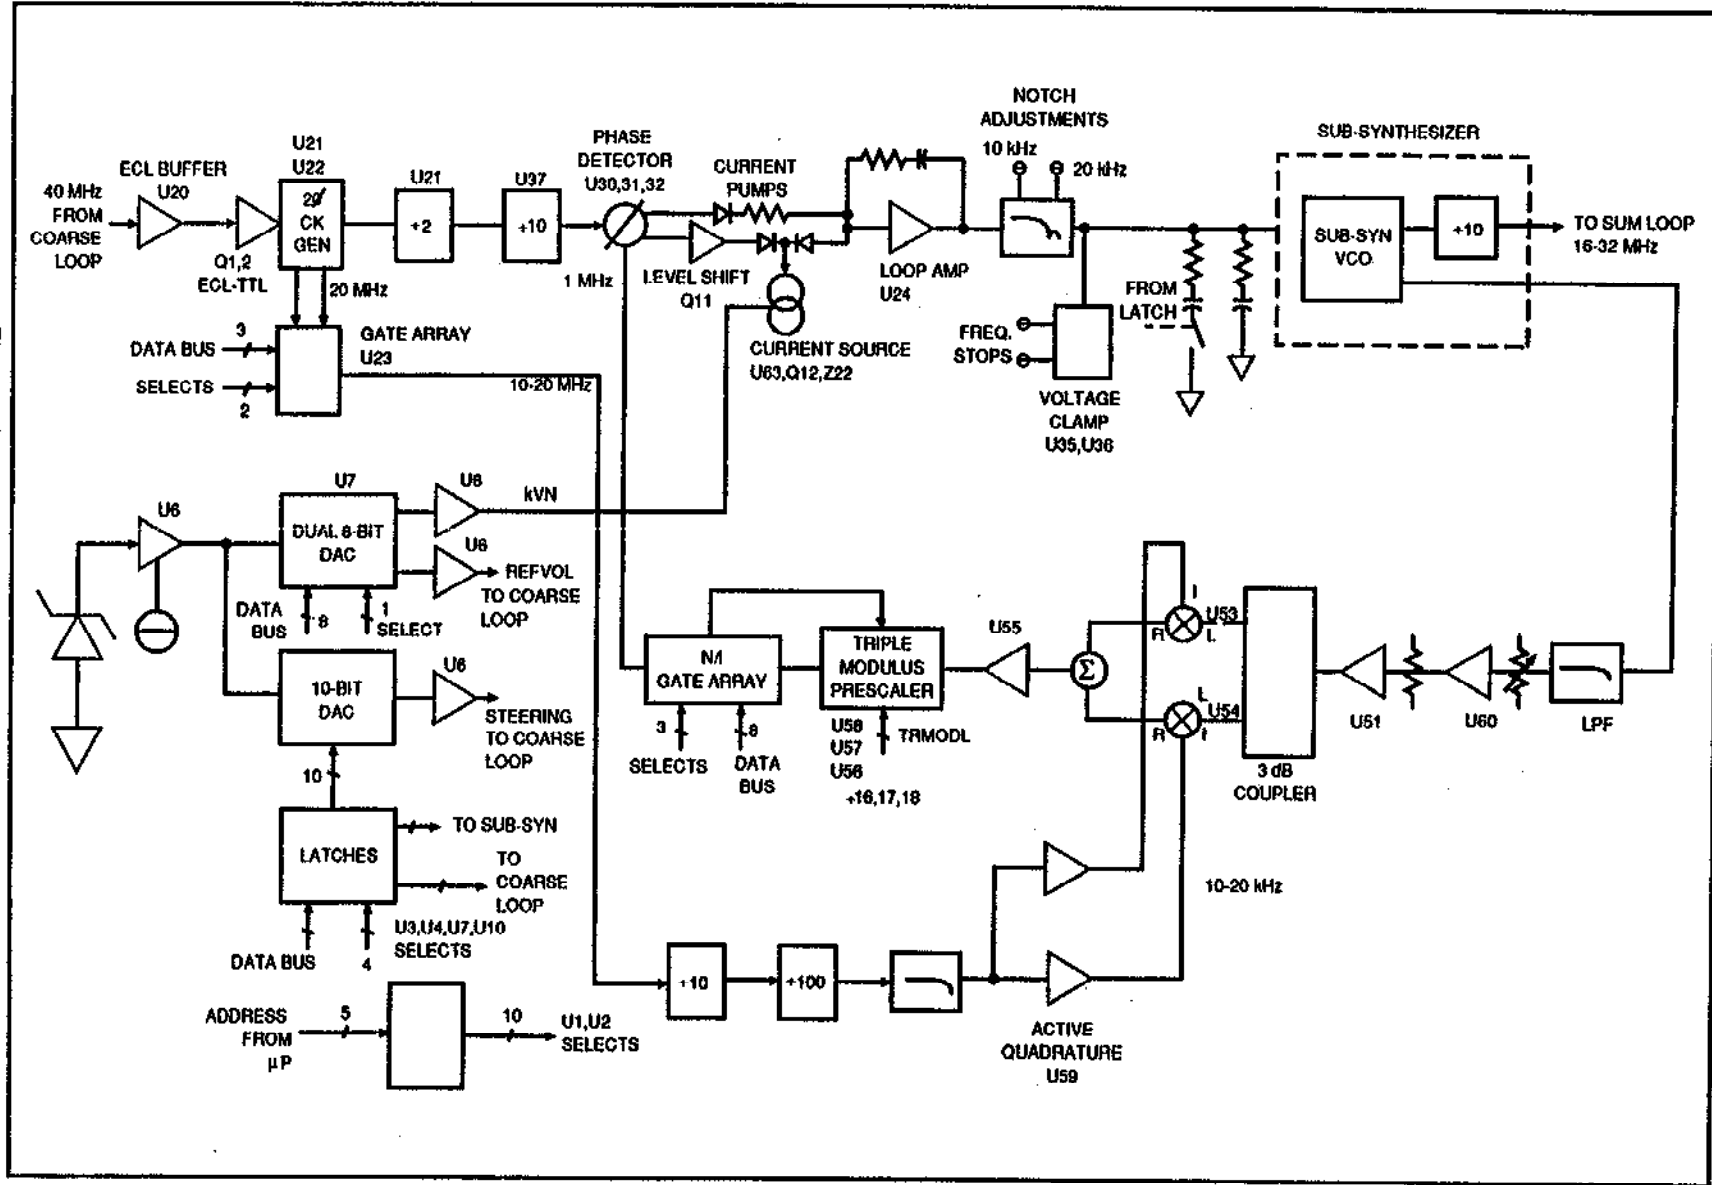

Figure 6C-2. Subsynthesizer Block Diagram

The output of U52 and two other audio quadrature signals from U59 are summed in the doubly-balanced mixers U53 and U54 to produce two double-sideband suppressed-carrier signals. Summing the two composite signals in the resistor network R75 and R76 suppresses the upper-sideband component because of the phase relationship of the outputs of the mixers. The predominant remaining signal is the lower-sideband signal.

The lower-sideband signal, spanning 160 to 320 MHz in 10 kHz steps, is amplified by U55 and applied to the N-divider where it is divided to 1 MHz.

## N-Divider

## 6C-5.

The main components of the N-Divider are: triple-modulus prescaler (divide by 16/17/18) U56, U57, and U58, and the N-Divider Custom Gate Array U62.

The triple-modulus prescaler (see Figure 6C-3), consists of divide-by-8/9 U58, divide-by-2 U57A, synchronizing flip-flop U57B, and quad NOR gates U56. If the inputs to U58, E1 through E5 (the 8/9 divider) are low, the prescaler divides by 9, and the total division to the output at pin 7 is 18.

If inputs E1 and E3 are low, the modulus of the 8/9 divider is controlled by the output of the divide-by-2 U57A. Consequently, the prescaler divides by 8 half the time and by 9 the other half, resulting in a divide by 17. U57B synchronizes the changing of the modulus with the clocking of the subsequent stages. The composite prescaler output U18A clocks the N-divider gate array via the ECL-to-TTL converter contained in U58.

The N-divider gate array (Figure 6C-4) contains two 5-bit binary counters (A and N), a BCD two-decade rate multiplier, and latches to interface to the controller. The following paragraphs describe the operation of the A and N counters.

At the beginning of a count cycle, a number is loaded into the A and N counters. The A counter is not at its terminal count, so the output is high, and the mode line (MODE L) is low. This causes the prescaler to divide by 17 (or 18, TRMODL=low). The mode line stays low for 31-A counts, where A is the programmed number. The mode line goes high, and the prescaler divides by 16 (or 17, TRMODL=low) for 31-N counts.

The total division is:

$$(P+1)(31-N) + P*((31-N)-(31-A))$$

or

$$P*(31-N) + (31-A).$$

On the 31st count, the counters are reinitialized. Figure 6C-5 shows the timing of the A counter programmed to 26 and the N counter programmed to 18, a total division of 213. Only the CKNL and MODEL signals shown in Figure 6C-4 are accessible at U62 pins 6 and 22, respectively.

The N-divider gate array includes a two-decade rate multiplier that produces the fractional part of the division. The N-divider gate array rate multiplier produces a pulse train with a programmed number of pulses for a 100-cycle frame of the 1-MHz N-divider output.

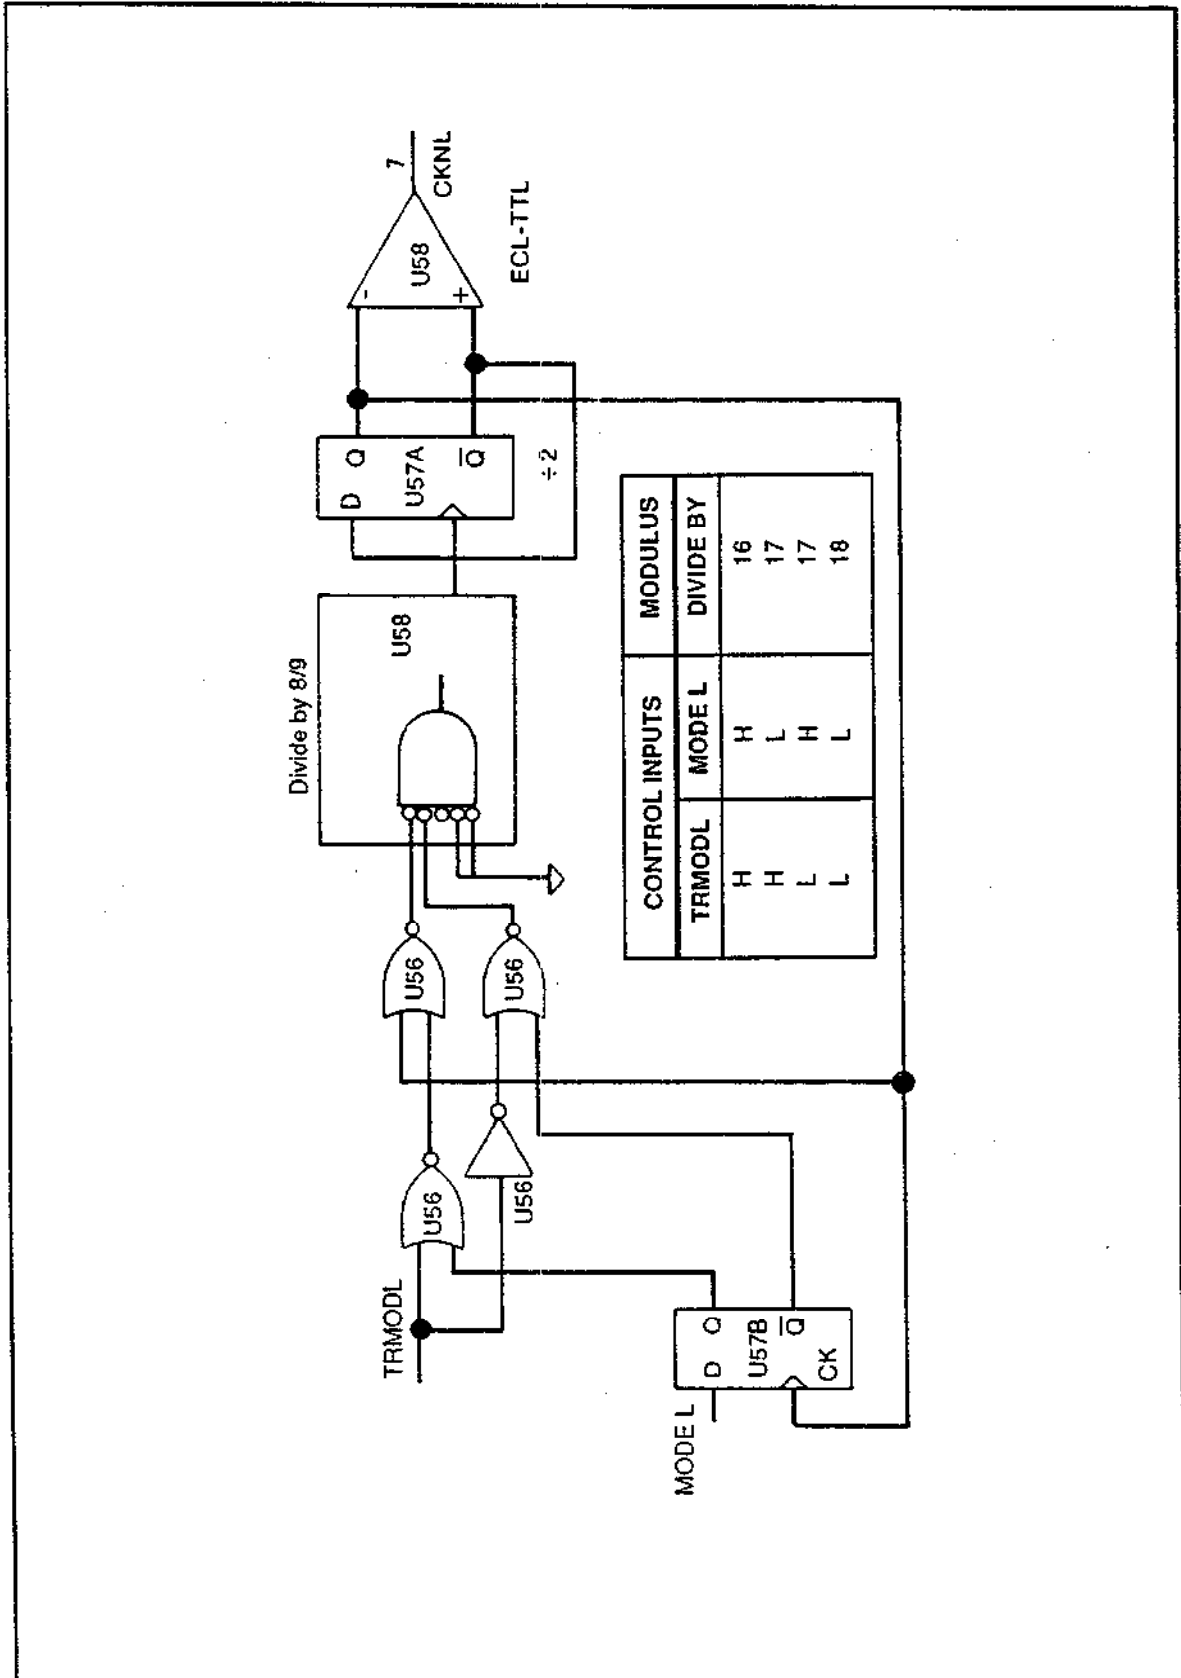

Figure 6C-3. Triple-Modulus Prescaler

Figure 6C-4. N-Divider

Figure 6C-5. N-Divider Timing Diagram

The programmed number ranges between zero and 99, corresponding to 10-kHz steps at the vco frequency. The flip-flops in the rate multiplier are set up on count 29, and on count 30 a pulse may or may not be present, depending on the programming of the rate multiplier. This is represented by the shaded pulse in the timing diagram (Figure 6C-5).

Irregularly spaced rate-multiplier pulses cause the mode line to go low, and the prescaler divides by  $P+1$  at a rate equal to the rate multiplier programming.

A 16/17 dual-modulus prescaler will not allow division from 160 to 320 without holes. For example, 170 is ten frames of 17. Consequently, there is no place to slip in the rate-multiplier pulses. It is not possible to divide by 171.

By using a triple-modulus prescaler, these problems are solved. Continuing with the previous example, 170 is 10 frames of 17 and 0 frames of 18. The deleter allows the prescaler to divide by 18 at a rate equal to the rate-multiplier frequency. Number 171 is 9 frames of 17 and 1 frame of 18. A software algorithm determines whether to operate in the 16/17 mode (TRMODL=1) or 17/18 mode (TRMODL=0).

The frequency at the output of the N-divider gate array is  $(F_o - F_s - F_d)/N$ . Since this must be equal to reference frequency,  $F_r$ , and  $F_r$  is 1 MHz, the vco frequency is  $F_o = N + F_s + F_d$ , where  $F_s$  is the SSB audio frequency from the low-order digit generator, and  $F_d$  is the fractional-division frequency.

### Phase Detector

6C-6.

The 1-MHz reference signal from divide-by-10 U37, and the 1-MHz signal from the N-divider U62 are connected to a digital phase-frequency detector made up of U30, U31, and U32. If the N-divider output frequency is less than the reference frequency, TP25 is low, and the voltage at the output of level shifter, Q17, is below ground. CR18 turns off and allows current from U63 to flow through CR18 out of the integrator. This raises the voltage at the output of the integrator, which raises the vco frequency.

Similarly, when the frequency of the N-divider output is higher than the 1-MHz reference, TP24 is high turning on CR16 and allowing current to flow through R97 into the integrator. This lowers the voltage at the output of the integrator, which lowers the vco frequency.

If the phase between the reference and N-divider output slips more than two cycles in either direction, the corresponding phase-detector output is either high or low. This provides twice the integrator current during acquisition as a conventional phase-frequency detector.

R51 provides a small bias current to the integrator to bias the phase detector in the linear region: consequently, the up-pump is always on.

During calibration of the vco, the vco gain coefficient ( $K_v$ ) is measured at many frequencies across the band, and non-volatile memory stores the compensation data. The instrument software uses this data along with N to control the PLL bandwidth. The PLL bandwidth is controlled by changing the current to the up-pump via KN dac (U7A, U6A), and voltage-to-current converter U62 and Q12.

**Loop Amplifier****6C-7.**

The loop amplifier-integrator consists of op amp U34, C98, and R44. Capacitors C97 and C102 filter the 1 MHz reference. The output of the integrator is connected to a multi-pole LC filter (R45, C104, C105, C106, C107, L56, L57, and R48) that attenuates the delete rate (10 and 20 kHz), and reference 1 MHz spurs.

Diodes CR12, CR13, CR14, CR15, CR22 and CR23 speed up the loop during switching. Additional lead/lag compensation is provided by C114, C115, R58, and R59. The second lead/lag network is switched by Q10 when the vco frequency is above 230 MHz. This compensates for the wide Kv range of the vco.

Amplifier U35 is a precision clamp that keeps the vco frequency within a specified range. Photoisolator U36 detects clamp activity, which indicates an out-of-lock condition. This signal is sent to the A13 Controller as the SUBUNLKL status.

**Low-Order Digits Generator****6C-8.**

The low-order digits generator consists of the clock generator (U21, U22, Q1, Q2), gate array U23, the divide-by-1000 (U60, U61), low-pass filter L75, and L76, and active quadrature generator U59. Internal to U23 is a 3 1/2 decade-rate multiplier, associated latches, and a divide-by-2.

The 40-MHz reference from the A2 Coarse Loop PCA is converted to ECL in U20 and then converted to TTL in Q1 and Q2. This is followed by a 20-MHz two-phase clock generator U21, U22.

The input frequency to the rate multiplier is 20 MHz. The output frequency can be programmed from zero to 19.995 MHz in 5-kHz steps. This signal is OR'd with the other phase of the 20-MHz clock to produce 20 to 39.995 MHz at U23 pin 1. The signal is also divided by 2 in U23, by 10 in U60, and again by 100 in U61 to produce 10 to 19.99975 kHz in 2.5-Hz steps (though not all of this resolution is used.) The TTL signal at TP30 is filtered by L75, L76, C156, C157, C158, C159, and C160. Op amp U59 forms an active quadrature generator to offset the signal at output pins 7 and 14 by 90 degrees. These two signals are the 10- to 20-kHz inputs for the PLL single-sideband mixer.

**Dac's and Latches****6C-9.**

The control bits for the A2 Coarse Loop PCA are latched by U3, part of U9 and U10. DAC U5 with op amp U6D provides the steering voltage for the A5 Coarse Loop VCO and dac U7B with op amp U6B provides the voltage to tune the reference TXCO.

**SUBSYNTHESIZER TROUBLESHOOTING****6C-10.****NOTE**

*All frequencies mentioned are synthesized; they are exact (coherent with the 10-MHz reference), unless noted as approximate.*

Status code 242 indicates that the A4 Subsynthesizer and/or the A3 Subsynthesizer VCO are/is not functioning properly. This status code is triggered when the Subsynthesizer VCO control voltage is out of the normal operating range. Status code 244 indicates the Sum Loop is out of lock, or that a problem exists with the Subsynthesizer and/or Subsynthesizer VCO.

## FREQUENCY SYNTHESIS

Status code 244, appearing without status code 242, might indicate a marginal break-up condition. To check the Subsynthesizer across the band, move the jumper on the A3 Subsynthesizer VCO from TP1-TP2 to TP1-TP3. This allows the undivided Subsynthesizer VCO frequency to appear at A3-J2.

Connect the A3-J2 output to a spectrum analyzer and program the Signal Generator to 800 MHz. Verify that a stable 160 MHz signal displays on the spectrum analyzer. Step the Signal Generator in 200-kHz steps, while stepping the spectrum analyzer in 4-MHz steps. At each point, verify that the spectrum analyzer displays a stable signal. If the signal shows evidence of breaking up, troubleshoot the Subsynthesizer and/or Subsynthesizer VCO.

If status code 242 appears, the vco control voltage may be stuck high or low. Measure the dc voltage at TP27 (it is not necessary to remove the module cover), if the dc voltage is around 1.5V, the circuitry that supplies the 1-MHz reference or the phase detector circuit is at fault. If the voltage is around 23V, check the circuitry associated with the phase-locked loop (vco, SSB mixer, and divider).

Table 6C-1 provides signal characteristics as seen at the various test points on the A4 Subsynthesizer PCA. The table lists the range of each signal and the expected value for a typical instrument state. The values in the TYPICAL column apply when the Signal Generator is programmed to 804.001499 MHz. To make the undivided Subsynthesizer VCO signal available for this troubleshooting procedure, move the jumper from TP1-TP2 to TP1-TP3 on the A3 Subsynthesizer VCO.

If the voltage at TP27 is approximately 1.5V, check TP22 for a 1-MHz TTL square wave. If the square-wave signal is missing or the frequency is incorrect, troubleshoot the circuitry previous to TP22. If the frequency is correct, check the phase detector (U30-U32) or loop amplifier (U34 and associated circuitry).

Check for a 10-MHz TTL square wave at U21 pin 9. The input at U21 pin 1, should be a 20-MHz TTL square wave. At U21 pin 3 there should be a 40-MHz TTL signal. There should be a 40-MHz ECL signal at both U20 pins 2 and 14. The A2 Coarse Loop input at J6, the frequency input, should be about 600-mV, p-p at 40-MHz.

If the Subsynthesizer VCO control voltage at TP27 is about 23V, remove the jumper shorting TP40-TP41 and connect a variable power supply to TP41 (be careful not to short to TP40, which could destroy U34). This opens the loop and allows the power supply to directly control the frequency of the Subsynthesizer VCO. Use a spectrum analyzer or counter connected to the undivided Subsynthesizer VCO output (A3-J3) to monitor the frequency. Adjust the power supply so that the frequency tunes from approximately 160 to 320 MHz. If the frequency cannot be adjusted, troubleshoot the A3 Subsynthesizer VCO. Set the frequency to approximately 240 MHz with the variable power supply.

Using a spectrum analyzer, low-impedance probe, and 10X attenuator, measure the level at the output of U51 (a good place to measure this is at the input to coupler U52). Ground the low impedance probe as closely as possible; PCA hold-down screws and the walls of the plate provide good grounds. The measured level should be approximately -10 dBm. If this level is not correct, troubleshoot the RF section (U50, U51, and associated circuitry).

Table 6C-1. Subsynthesizer PCA Test Points

Typical: Front panel frequency set to 804.001499 MHz Range: Total Subsynthesizer frequency range (160-320 MHz) Front panel from 800.000000 to 807.999999 MHz				
TEST POINT	SIGNAL TYPE	RANGE	TYPICAL	FUNCTION
TP2	ground			
TP3	TTL	20 MHz, 12.5 ns (AH)	Constant	2-phase clock generator
TP4	TTL	20 MHz, 12.5 ns (AH)	Constant	2-phase clock generator
TP5	TTL	10 to 19.98 MHz	19.98 MHz	Low order digit gate array output
TP6	DC	0 to 10.23V	2.2V	Coarse Loop VCO steering dac output
TP21	TTL	1 MHz, 50 ns (AL)	1 MHz	N-Divider output
TP22	TTL	1 MHz square wave	1 MHz	Reference divider output
TP23	Ground			
TP24	TTL	1 MHz, 10 ns (AH)	1 MHz	Phase detector down output
TP25	TTL	1 MHz, 150 ns (AH)	1 MHz	Phase detector up output high ~2.8V, low ~-0.5V
TP26	Ground			
TP27	DC	2 to 24V	8.6V	Subsynthesizer VCO control voltage
TP30	TTL	10 to 19.98 kHz	19.98 kHz	Low order digits signal
TP31	TTL	1 to 1.998 MHz	1.998 MHz	Intermediate low order digits signal (divide-by-10)
TP32	Ground			
TP33	TTL	9 to 19 MHz	15 MHz	Triple modulus pre-scaler output
TP34	TTL	0 to 1 MHz	10 kHz 50 ns (AL)	Modulus select signal
TP35	DC	0 to 10.23V	1.6V	Subsynthesizer loop gain compensation dac (KN) output
TP36	Input			For calibration of low-pass filter
TP37	Audio	10 to 19.98 kHz 450 mV p-p	19.98 kHz	Active quadrature generator output
TP38	Audio	10 to 19.98 kHz 450 mV p-p	19.98 kHz	Active quadrature generator output
TP39	DC	0 to 10.23V	Varies	Reference oscillator voltage dac output
TP40	DC	2 to 24V	8.6V	Loop amplifier output
TP41	DC	2 to 24V	8.6V	Low-pass filter input TP40-TP41 normally connected together, except when troubleshooting

Next, check the signal at the input to the divider U58 at pin 15 with the low impedance probe. Verify a -15 dBm lower sideband signal as measured on the spectrum analyzer. A problem at this point indicates a failure in the low order digits generator (U21, U22, U23, U60, and U61), active quadrature generator U59, SSB mixer U53, and U54, or divider input amplifier U55.

## FREQUENCY SYNTHESIS

Program the Signal Generator to 804.000500 MHz. Verify the TTL signal at the output of the triple modulus prescaler, TP33, is approximately 15 MHz. The signal at the output of the N-divider gate array, TP34, should be approximately 1 MHz. This frequency should change as the 1-MHz digit is programmed, since the divide ratio is changing.

To troubleshoot the low-order digit generator, check the signal at TP3 and TP4 for a 25% duty cycle, active high 20-MHz TTL signal. Program the Signal Generator to 800.000000 MHz. The signal at TP5 should be 10-MHz TTL. As you program the unit under test (UUT) to 1 Hz, 10 Hz, and 100 Hz digits, the frequency at TP5 should change by 20 kHz, 200 kHz, and 2 MHz, respectively.

When the UUT is programmed to 800.000499 MHz, the frequency at TP5 should be 19.98 MHz. The outputs of the two divide-by-10, U60 and U61, should be 1.998 MHz and 19.98 kHz, respectively. The output of active quadrature generator U59 at TP37 and TP38 should be about 450 mV p-p, 19.98-kHz sine waves.

Tune the power supply and monitor the frequency at TP21; if the frequency is less than 240 MHz, the frequency at TP21 should be less than 1 MHz. There should be a TTL signal at TP24 that is predominantly low with very narrow pulses going high. There should be a similar signal at TP25, except the "low" voltage is approximately -0.5V and the "high" voltage is +2.8V. The voltage at TP40 should be about 28V.

If the frequency is greater than 240 MHz, the frequency at TP21 should be greater than 1 MHz. The signal levels at TP24 and TP25 should be predominantly high. The voltage at TP40 should be about -2V.

If the signals at TP24 and TP25 are correct, but the voltage at TP40 does not change from approximately -2V to +28V as the frequency at TP21 is adjusted above and below 1 MHz, troubleshoot the following circuits:

- Loop amplifier U34 and associated circuitry
- Current source U63 and associated circuitry
- Switching diodes CR18 and CR19
- KN dac U6
- U7 and associated circuitry.

The loop should lock when you reconnect the shorting jumper between TP40 and TP41. If the loop does not lock, check low-pass filter L56, and L57 (and associated circuitry), clamp circuit U35 and U36 (and associated circuitry), and the lead-lag network. FET Q10 should be on (~+5V on the gate) when the undivided Subsynthesizer frequency is less than 230 MHz, and off (~0V on the gate) when the frequency is greater than 230 MHz. Disconnect CR20 and CR21 to disable the clamp circuit.

To check the various dac's, program the UUT to SPCL 943. This sets all the dac's to full scale. The voltage at the output of the KN dac (TP35), REFVOL dac (TP39) and STEERING dac (TP6) should be approximately 10.23V. When the UUT is programmed to SPCL 942, dac's to half scale, these voltages should be about 5.12V.

**SUBSYNTHESIZER ADJUSTMENTS****6C-11.**

The following procedures describe the five adjustments on the A4 Subsynthesizer PCA. These adjustments are as follows:

- R5, Steering dac full-scale adjustment
- R99, Lower clamp adjustment
- R98, Upper clamp Adjustment
- R106, SSB mixer LO drive adjustment
- L56, 10-kHz notch adjustment

**NOTE**

*These adjustments are not routine and are required only when you replace the associated components or when you change the adjustment.*

**Steering DAC Full-Scale Adjustment****6C-12.****TEST EQUIPMENT:**

- DVM

**REMARKS:**

The steering dac full-scale adjustment is normally required only when U5, U6, or associated components have been replaced, or when the adjustment has shifted.

**PROCEDURE:**

Adjust the steering dac voltage to 10.23V with the coarse loop steering dac set to full scale.

1. Program the UUT to SPCL 909.
2. Program the UUT to SPCL 943. This Special Function programs all dac's to full scale.
3. Connect the dvm to measure voltage between TP6 and ground.
4. Adjust R5 for  $10.23V \pm 0.01V$ .
5. Program the UUT to SPCL 00. This clears all Special Functions.

**Lower Clamp Adjustment, R99****6C-13.****TEST EQUIPMENT:**

- Frequency counter

**REMARKS:**

The lower clamp adjustment, R99, is normally required only when replacing U35, U36, or associated components, when the A3 Subsynthesizer VCO has been repaired or replaced, or when the adjustment has shifted.

## FREQUENCY SYNTHESIS

### PROCEDURE:

Adjust the lower clamp frequency to 15 MHz with the reference to the phase detector disabled.

1. Connect output (J4) of the A3 Subsynthesizer VCO to the frequency counter. Set the frequency counter to measure with 1-kHz resolution.
2. Program the UUT to SPCL 909.
3. Program the UUT to 800 MHz. The frequency counter should read 16.000 MHz.
4. Short TP22 to ground.
5. Adjust R99 for a frequency counter reading of 15.000 MHz  $\pm$ 10 kHz.

### Upper Clamp Adjustment, R98

6C-14.

#### TEST EQUIPMENT:

- Frequency counter

#### REMARKS:

The upper clamp adjustment, R98, is normally required only when replacing U35, U36, or associated components, when the A3 Subsynthesizer VCO has been repaired or replaced, or when the adjustment has shifted.

### PROCEDURE:

Adjust the upper clamp frequency to 32.5 MHz with the N-divider signal to the phase detector disabled.

1. Connect the J4 output of the A3 Subsynthesizer VCO to the frequency counter. Set the frequency counter to measure with 1 kHz resolution.
2. Program the UUT to SPCL 909.
3. Program the UUT to 640 MHz. The frequency counter should read 32.000 MHz.
4. Short TP21 to ground.
5. Adjust R98 for a frequency counter reading of 32.500 MHz  $\pm$ 10 kHz.

### SSB Mixer LO Drive Adjustment, R106

6C-15.

#### TEST EQUIPMENT:

- RF Probe (10X)
- Spectrum analyzer

**REMARKS:**

The SSB mixer LO drive adjustment, R106, is normally required only when replacing U50, U51, or associated components, when the A3 Subsynthesizer VCO has been repaired or replaced, or when the adjustment has shifted.

**PROCEDURE:**

Measure the SSB mixer LO Power with a 10X RF probe using a spectrum analyzer. Adjust the SSB mixer LO Power to -10 dBm as displayed on the spectrum analyzer. This corresponds to +10 dBm at the input to the coupler.

1. Program the UUT to SPCL 909.
2. Program the UUT to 800 MHz.
3. Connect the 10X RF probe to the input of the spectrum analyzer. Set the spectrum analyzer to -5 dBm reference level, 160 MHz, 1 MHz span, and 1 dB/div.
4. Touch the probe tip to the input of the coupler, U52, which connects to C147. This is best done on the top of the coupler with the ground connection on the coupler ground plane.
5. Adjust R106 for -10 dBm as displayed on the spectrum analyzer.

**10-kHz Notch Adjustment, L56****6C-16.****TEST EQUIPMENT:**

- Spectrum analyzer

**REMARKS:**

The 10 kHz notch adjustment is normally required only when L56, L57, and associated components have been replaced, or when the adjustment has shifted.

**PROCEDURE:**

A signal from the internal modulation oscillator is injected into the Subsynthesizer phase detector to produce a 10-kHz spur. Adjust L56 to minimize this spur.

1. Program the UUT to SPCL 909.
2. On the A3 Subsynthesizer VCO, move the jumper near J2 from TP1-TP2 to TP1-TP3. Reattach the cover on this side of the module.
3. Program the UUT to 800 MHz, modulation frequency 10 kHz, modulation level 100 mV. Connect the front panel MOD OUTPUT to TP36 on Subsynthesizer PCA.
4. Set spectrum analyzer to center 160 MHz, reference level 5 dBm, frequency span 100 kHz. The signal should be visible in the center of the screen with 10-kHz sidebands.

5. Adjust L56 to minimize these 10-kHz sidebands.
6. On the A3 Subsynthesizer VCO, move the jumper (near J2) back to TP1-TP2.

### A3 SUBSYNTHESIZER VCO CIRCUIT DESCRIPTION

6C-17.

The A3 Subsynthesizer VCO PCA is controlled by the A4 Subsynthesizer PCA and produces a signal that is further processed in the A12 Sum Loop PCA. This assembly includes a varactor-tuned oscillator that generates frequencies from 160 to 320 MHz, along with low-pass filters and an ECL divide-by-ten circuit.

Q1 is configured as an oscillator, with a tunable resonant circuit connected between the base and collector to provide positive feedback. This circuit includes printed transmission lines, varactor diodes CR1-CR4, and inductor L1. The frequency tuning voltage at J1-4 is applied to the varactor diodes through RF choke L2, and tunes the oscillator over a 160 to 320 MHz range with voltages from about 2 to 22V.

The oscillator transistor output signal at Q1 emitter is next applied to Q2, configured as a common-base stage that provides isolation. The 0 dBm output of Q2 is applied to monolithic amplifier U1, which boosts the signal level to +13 dBm at its output.

Two switched low-pass filters, including PIN diodes CR5-CR8 and capacitors C13-C22, follow U1 and provide harmonic suppression. Comparator U4 senses tuning voltage VT, and enables the low band filter between CR5 and CR6 for VT less than 7.5V, and enables the high band filter between CR7 and CR8 for VT greater than 7.5V. The 7.5V switching voltage, corresponds to about 230 MHz.

The filtered signal is next applied to resistive splitter R13-R17. One output drives monolithic amplifier U2, which provides isolation and boosts the signal to about +7 dBm. This signal connects to the A4 Subsynthesizer PCA by a through-the-plate coaxial connector at P1. The other splitter output drives ECL divide-by-ten frequency divider U3. The divided output signal from U3 ranges in frequency from 16 to 32 MHz and is filtered by a five-element low-pass filter (L5, L6, C27-C29). The output signal connects by way of a coaxial cable to the A12 Sum Loop PCA at J2.

### SUBSYNTHESIZER VCO TROUBLESHOOTING

6C-18.

A problem in the Subsynthesizer VCO can cause uncal status response 242 (Subsynthesizer unlock) and can also cause self-test failure 324. To test the vco independent of the Subsynthesizer PCA, connect a voltage source, such as an external power supply, to the phase lock port at J1 pin 4. This will override the voltage supplied by the Subsynthesizer PCA but will not damage the UUT. Vary the phase lock voltage from 2 to 23V, and observe the signal at connector J2 on a spectrum analyzer. Verify that the frequency varies from about 16 to 32 MHz, and that the level is about +2 dBm. If the signal does not change as described, troubleshoot the vco.

As a first step in troubleshooting, remove the plug-on jumper from TP1 to TP2, and install it to connect TP1 to TP3. This bypasses divider U3, and connects the fundamental oscillator signal to J2. (Remember to plug the jumper into its original position after troubleshooting.) This signal should vary from about 160 to 320 MHz at about +3 dBm over the tuning range. If this signal does not appear as described, troubleshoot the circuitry previous to the input of U3. Measure the dc voltages at various nodes in the circuit to help isolate the failed circuit. Table 6C-2 lists expected approximate dc voltages at various circuit nodes.

Table 6C-2. A3 Subsynthesizer VCO PCA DC Voltages

LOCATION	VOLTS DC
Q1 collector	+8.7
Q2 collector	+7.1
U1 output	+3.9
CR5/CR7/R10 node, V(phase-lock) $\sim$ <7.5V	+2.3
CR5/CR7/R10 node, V(phase-lock) $\sim$ >7.5V	-2.3
U2 output	+4.4
U3 pin 2	+3.5

**A2 COARSE LOOP CIRCUIT DESCRIPTION**

**6C-19.**

The Coarse Loop PCA generates frequencies from 576 to 960 MHz in 8-MHz steps. It also provides a 40-MHz reference for the Subsynthesizer, a 20-MHz signal for the modulation oscillator, and an 80-MHz signal for the output section. This 80-MHz signal is the local oscillator signal for the heterodyne band and is the reference for the FM circuitry.

The PCA consists of two major blocks: the reference section and the coarse loop. These blocks are described in the following paragraphs.

**Reference Section**

**6C-20.**

Refer to the Reference Section Block Diagram (Figure 6C-6) and the Coarse Loop PCA schematic diagram in Section 10 to identify major functional sections and to follow the signal paths of the coarse loop reference section.

The reference section is a phase-locked loop which includes a 40-MHz voltage-controlled crystal oscillator (VCXO), a divide-by-4, by-8, by-20, by-40, a digital phase frequency detector, and associated logic.

The main frequency reference for the instrument is either internal or external. The internal reference is a 10 MHz temperature-controlled crystal oscillator (TCXO), U501, or either the High-Stability (Option -130) or Medium-Stability (Option -132) ovened references. An external reference can be used in place of the internal 10 MHz reference, and can be 1, 2, 5, or 10 MHz.

When the instrument is set to internal reference (EXTREFH=0), the TCXO is turned on by enabling Q501 via open-collector comparator U509C and associated logic circuitry, U502 and U514. The 10-MHz signal from the TCXO is routed through U502 to multiplexer U504B. The output of the multiplexer is connected to the reference clock input of phase detector U503A and U511D.

If the optional high or medium-stability reference is installed (TCXOH=0), the TCXO is disabled. The 10 MHz signal from the optional reference is routed from J8 (REF IN BNC connector) to the phase detector.

When the instrument is set to external reference (EXTREF=1), the TCXO is turned off. The external signal from J6 is attenuated by R521 through R523, then clipped by CR501 and CR102, and input to a high-pass filter made up of C524 and C525, and L502. High-speed comparator U510 converts the external reference signal to TTL. The output of U510 is input to multiplexer U504B. A portion of the comparator output is fed back to the input to provide hysteresis (R524-R527).

The 40-MHz voltage-controlled crystal oscillator (VCXO) consists of four parts: the 40-MHz third-overtone crystal Y601, a grounded base stage made up of Q606 and associated components, a low-Q tuned circuit to ensure the crystal operates at the third overtone made up of L601, C604 and C605, and R602, and varactors CR603 through CR605.

This oscillator can be tuned approximately  $\pm 1$  kHz. Feedback is from collector to emitter. The output from the collector-tuned circuit is lightly coupled by C607 to buffer amplifier U601. The output of the buffer is connected to the 80-MHz section (R606, R617, C610) and another pair of grounded base stages Q607 and Q608. The outputs of these buffers are filtered by a low-pass filter made up of C616, C617, L604, C622, C623, and L605. The output of Q608 is converted to ECL in U602, while the other output drives the main loop phase detector buffer amplifier Q205.

One output of U602 provides the 40-MHz reference for the A4 Subsynthesizer via J16. The same output is also clocked into U506A, divided by 2, and buffered by U513. The 20-MHz square wave is output to bandpass filter R536, L510, and C545 before being sent to the A6 Modulation Oscillator via J8.

A second divide-by-2 counter (U506B) divides the 20 MHz to 10 MHz. This ECL signal is converted to TTL by Q504 and Q505 and buffered by U507C. Two inverters in parallel (U507A,B) drive a low-pass filter consisting of C518, C519, C550, and L501. This filter outputs a 10-MHz sine wave, which is the reference out for the instrument (J7).

When in internal reference, the 10-MHz signal from U507C is routed through multiplexer U504A to the CK input of phase frequency detector U503B, and U511D. When in external reference (10 MHz), divider U505 is disabled and the signal from U507C is routed through multiplexer U504C and logic circuit U511A,B to the R input of the phase frequency detector.

When Special Function 761 is enabled, the 10-MHz signal is divided to 1 MHz, 2 MHz, or 5 MHz by U505, depending on how the switches in SW502 are set. The output of the divider is also routed to the phase frequency detector.

Phase frequency detector U503 and U511D compares the phase/frequency of the divided 40-MHz VCXO (V input) with either the 10-MHz TCXO, the high or medium stability optional reference, or an external reference. The phase detector operates at 10 MHz, except when an external reference of 1, 2, or 5 MHz is used. In these cases, it operates at the reference frequency.

The output of this phase detector operates in the differential voltage mode. If the frequency/phase of the V input (U503B pin 11) is greater than the R input (U503A pin 3), there will be a net positive voltage from U503A pin 6 to U503B pin 8. The loop amplifier/integrator (U508 and associated components), which drives a lead-lag network made up of R532, R530, C546, and Q502, integrates the phase detector voltage and causes the voltage on the control line to varactors CR603 through CR605 to drop until the two frequencies match and the loop is locked. Consequently, if the frequency/phase of the R input is greater than the V input, the net voltage will be negative, and the control voltage will rise until the loop is locked.

A small phase offset is set (R512) to keep the phase detector in its linear region. The bandwidth of this reference loop is changed by switching in various lead-lag networks (R505, R510, R530, R532, C530, C547, C549, C546). When in internal TCXO or external 10 or 5 MHz, Q506 and Q502 are on and the loop bandwidth is approximately 30 Hz. When the external reference is 1 or 2 MHz, Q506 is on and Q502 is off. Turning off Q502 increases the gain by five times, but since the division factor is five times greater, the overall loop gain remains approximately constant. When the medium or high stability optional internal reference is active, both Q502 and Q510 are off and the loop bandwidth is approximately 500 Hz.

The loop control voltage (U508 pin 6) is sensed by two comparators U509A,B. If the voltage is less than approximately 1.2V and more than approximately 11V or if the voltage is pulsing, the loop is unlocked. One-shot U512 converts these pulses into a logic signal. This is combined with the low and high voltage detector to produce REFUNLKL, which is sent to the controller.

The 40 MHz from buffer U601 is amplified by Q609 and doubled to 80 MHz by full-wave rectifier T601, CR601, and CR602. The 80 MHz is filtered by L611, L612, C643, and C644. Then the 80 MHz is amplified by Q610, and filtered again by C649, C50, L613, and L615. This 80-MHz signal is sent to the output section via J5. When in the dc FM mode and not in the heterodyne band, this signal is turned off by Q611 via the REF80H signal.

### Coarse Loop

6C-21.

Refer to the Coarse Loop Block Diagram (Figure 6C-7) and the Coarse Loop PCA schematic diagram in Section 10 to identify the major functional sections and follow the signal paths of the coarse loop.

The coarse loop consists of two interlocking loops: the main phase-locked loop and the discriminator loop around the vco. (The discriminator loop reduces the phase noise of the vco.)

A 576- to 960-MHz signal from the A5 Coarse Loop VCO is attenuated, amplified by U401, attenuated again, and amplified a second time by U405. This signal drives divide-by-4 prescaler U301. The 144- to 240-MHz output of the prescaler is amplified to ECL levels by U311 and is input to the N-divider.

The main N-divider consists of two parts: a programmable divide by 3/4/5/6/7 (made up of U302, U303, U308, and U310), and a programmable 5-bit rate multiplier (made up of U304, U305, U306, and U307). The divide by 3/4/5/6/7 is a ring counter with different feedback paths selected to change the division. It is programmed with the CF0/CF1 bits to a steady-state value of  $N = 3, 4, 5, \text{ or } 6$ . A toggle line (TP2) allows the divider to be programmed to one more than its steady-state value ( $N+1$ ).

## FREQUENCY SYNTHESIS

The rate multiplier generates a sequence of 0 to 19 pulses within a 40-MHz frame. The output of the rate multiplier drives the TP2 toggle line. Consequently, the divider divides by N part of the frame and N+1 for the remainder of the frame. Fractional division with a 2-MHz step size is obtained depending on the programming of the rate multiplier. Because of the divide-by-4 prescaler, this corresponds to a 8-MHz step at the Coarse Loop VCO frequency.

The outputs of N-divider U308D are connected to mixer phase detector U203. The 40 MHz from the reference section is buffered in a common base stage Q205 and amplified by Q206 to provide a second input to the phase detector. The output of the phase detector is input to the low-pass filter, C212 through CR216 and L204 and L205, with notches at 2 and 4 MHz to suppress the rate multiplier spurs. A lead-lag network made up of R210, R211, and C211 provides proper high-frequency termination for the mixer.

The output of the low-pass filter is connected to loop amplifier U205. This amplifier provides lead-lag compensation for the phase-locked loop. The output of this stage is fed into the acquisition oscillator stage U206. This is set up as a Wien bridge oscillator consisting of R225 through R228, C228 and C229 at a frequency of approximately 100 Hz. Since the phase detector is not a phase/frequency detector, the beat frequency at the output of the phase detector must be small in order for the loop to lock. When the loop is unlocked, the Wien bridge oscillator is oscillating, and the vco frequency is slowly swept about its steered frequency. This causes the beat frequency to be slowly swept close to 0. When the loop locks, there is enough gain around the loop so the oscillation condition for the Wien bridge is no longer met and it stops oscillating. One-shot U204 trips when the Wien bridge oscillates to indicate an out-of-lock condition. This signal (CORUNLKL) is sent to the controller.

The output of the acquisition oscillator U206 is fed into a programmable lead-lag network made up of R229 through R237, C231 through C235, and Q201 through Q204. Since the tuning slope of the vco, in MHz/V, is not constant, this network is programmed to reduce the magnitude of the change. The output of this network is connected to the phase-lock port of the A5 Coarse Loop VCO via J4. This network forms part of the compensation of the discriminator loop. Comparator U208 converts the TTL programming input to 0/10V to drive the FETs. Comparator U210 monitors the phase-lock voltage and generates signals when the voltage exceeds -5V (CORVOLH) or +5V (CORVOLL). This voltage is used for the Coarse Loop VCO compensation.

A 500-Hz active Bessel filter, U207, amplifies and filters the steering voltage from the A4 Subsynthesizer PCA, input via J1-16. The same signal is then sent to the A5 Coarse Loop VCO via J15.

The discriminator circuit senses the frequency noise of the vco and generates a correction signal to reduce the noise. A portion of the RF output from the Coarse Loop VCO (P2) is amplified by U402 and fed into the two-stage limiting power amplifier Q405 and Q406. The output of the amplifier is filtered by C422 through C426, CR402, and CR403. This filter switches at 712 MHz, the same point as a vco band change. Op amp U209 drives PIN diode switches CR402 and CR403.

The output power from the filter is approximately +20 dBm to the 90-degree power splitter on the A25 Discriminator Board. The outputs of the power splitter are connected to the LO input of the mixer U404 and to the delay cable. The other end of the delay cable is connected to the RF input of the mixer. The delay cable is trimmed, so as the coarse loop steps in 8-MHz increments, the phase is such that the IF output is approximately 0V dc.

A filter made up of C418 through C421, L403, L404, R419, and R420 is connected to the IF port. This filter provides both UHF and HF terminations for the mixer. The output of the filter is ac-coupled by C101 and R106 to low noise amplifier Q101 through Q106. The output of this amplifier is resistively summed at R123 and R125 with the phase lock voltage from U206. Diodes CR101 and CR102 limit the output of the discriminator amplifier while in the acquisition mode. To ensure stability, the gain of the low noise amplifier is rolled off by C104 and R119.

## COARSE LOOP TROUBLESHOOTING

6C-22.

The A2 Coarse Loop consists of two sections: the reference section and the main coarse loop. These sections are described in the following paragraphs.

### Reference Section

6C-23.

A status code 246 indicates a problem in the reference section. This code is displayed when the Signal Generator is set to external reference but no reference is supplied. It is also displayed if the reference is the wrong frequency or is outside the lock range specification. If the unit is set to internal reference and the high or medium stability option is installed, check to see that the 10-MHz output from the option is correct.

If the voltage at TP19 measures approximately -13V, it indicates a problem with the internal TCXO, the internal/external reference circuitry, or the phase detector/loop amplifier. If the voltage measures approximately 13V, it indicates a problem in the 40-MHz oscillator, buffers, dividers, or phase detector/loop amplifier.

Use a 10M $\Omega$ , 8 pF probe and make a ground connection, less than 1 inch of lead length, at the probe tip. Voltages measured with an oscilloscope are approximate. Because the reference loop is not locked, frequencies given here are not exact and will typically be slightly higher than indicated. Check the oscillator for 40 MHz 1.4V p-p at TP4.

To check the reference circuitry, proceed as follows:

1. Check the junctions of L605 and C624, L604 and C625, and C617 and C625 for a 630 mV p-p signal.
2. Check U602 pin 2 for a 40-MHz ECL signal.
3. Check TP17, which connects to the A4 Subsynthesizer, for a 700 mV p-p signal.
4. Check the output of the first divide-by-2, U506 pin 15, for a 20-MHz ECL square wave.
5. At TP17 following buffer U513, which supplies the A6 Modulation Oscillator, check for a 20 MHz, 1.2V p-p signal.
6. At U506 pins 2 and 3 check for a 10-MHz ECL square wave.

## FREQUENCY SYNTHESISIS

7. At the collector of Q505, check for a 10-MHz TTL signal.
8. At J7, the 10 MHz OUT connector, check for a 10-MHz 5V p-p sine wave.
9. If the voltage at TP19 is approximately -13V when in internal reference, first check the internal TCXO. There should be a 10-MHz TTL signal at U502 pin 12 and U503 pin 3. Power to the TCXO is supplied from Q501 at TP18.

### NOTE

*If the optional medium or high stability reference is installed, no power should be supplied to the TCXO and there should be a 10 MHz TTL signal at J8 and at pin 3 of U503.*

10. If the instrument is set to internal or external 10-MHz reference, REFSEL should be a logic high. There should be a 10-MHz TTL signal at the phase detector input, U503 pin 11.
11. If the instrument is set to the 1-MHz, 2-MHz, 5-MHz external reference mode (SPCL 761), REFSEL should be a logic low. The signal at U503 pin 11 is 1, 2, or 5 MHz (configured for 5 MHz at the factory), depending on the setting of SW502. Refer to the alignment section for information on how to set this switch.
12. To check the external reference, connect a 10-MHz source, +4 dBm signal to the REF IN connector. There should be a 1V p-p sine wave at J6. There should be a 10-MHz TTL signal at U510 pins 9 and 11 and eventually at U503 pin 5. The logic control for the reference section is summarized in Table 6C-3.

Table 6C-3. Reference Section Logic Control Line Summary

STATE	EXTREFH	TCXOH	REFSEL	Q502	Q506
External 10 MHz	1	Y	1	On(+5V)	On(+15V)
External 5 MHz	1	Y	0	On	On
External 2 MHz	1	Y	0	Off(0V)	On
External 1 MHz	1	Y	0	off	On
Internal TCXO	0	1	X*	On	On
Internal HI/MED ref	0	0	X	Off	Off

X = 1 if using 10 MHz external reference; 0 if using SPCL 761 (1, 2, or 5, MHz external reference).  
 Y = 1 if using standard TCXO; 0 if using high or medium stability option

13. You should observe 10-MHz signals at U503 pins 3 and 11. To check the phase detector, remove the jumper between TP20 and TP21. Connect a variable power supply to TP21. Monitor the frequency at U503 pin 11. As you adjust the power supply from about 1 to 10V, the frequency at TP11 should increase and decrease around 10 MHz by about  $\pm 200$ -500 Hz. The voltage at TP19 should range between -13 and +13V. Reconnect the jumper between TP20-TP21.

14. The final check is the out-of-lock circuitry, which consists of U509, U512, and U515. When the control voltage is between 1 to 11V, the signal at J2-2 should be a TTL high.

To troubleshoot the 80-MHz doubler section, proceed as follows:

1. Check the bias voltages. The voltage should be about 8.8V at the junction of R648, C652, and T601. The voltage at the collector of Q610 should be about 8.1V.
2. Check for the collector of Q609 for an ac voltage of 40 MHz, 2.7V p-p.
3. Check the output of the doubler CR601 and CR602 for an 80-MHz full-wave rectified signal of 1.2V p-p.
4. Check for an 80-MHz 0.8V p-p sine wave at J5.

**Main Loop**

**6C-24.**

Status code 243 indicates that the coarse loop is out of lock. Status codes 244 or 245, which indicate the sum loop is out of lock, could be caused by a marginal lock condition in the coarse loop.

When any of these codes are present, check the coarse loop steering circuit first, as follows:

1. Program the coarse loop to 640 MHz by setting the UUT to 544 MHz.
2. Connect the output of the Coarse Loop VCO, A2-J8, to a spectrum analyzer.
3. Ground the phase lock port, TP7 and disable the search oscillator by moving the jumper from TP13 to TP28-TP13.
4. There should be a signal at 640 MHz  $\pm$  2 MHz. If the signal is absent or it is far off frequency, either the Coarse Loop VCO or the vco steering voltage circuit has failed.
5. Program the UUT with SPCL 943 and measure the dc voltage at TP8, the vco steering port. This special function programs the steering dac to full scale, and should result in a reading of 24V. If the Coarse Loop VCO seems to function properly, the Coarse Loop PCA is probably at fault.
6. Using a 500 $\Omega$ , 10X probe connected to the spectrum analyzer, compare the levels in the RF section with those in Table 6C-4. These levels are as measured on the spectrum analyzer. The actual level is 20 dB higher.

Table 6C-4. Coarse Loop RF Levels

CONNECTION POINT	LEVEL
P2	-14 dBm
U401 output	-18 dBm
U405 output	-16 dBm
U402 output	-16 dBm

### NOTE

*The levels in Table 6C-4 are approximate and can vary as much as  $\pm 3$  dB.*

7. At the output of the divide-by-4 amplifier, use a 500 $\Omega$ , 10X probe to check for a 160 MHz, -16 dBm signal.
8. The N-divider programs the coarse loop in 8-MHz steps. The output of the N-divider, TP1, should be approximately 40 MHz, ECL level. There should not be any signal at TP2 for coarse loop frequencies of 640 MHz, 800 MHz, and 960 MHz.
9. If the rate multiplier divider (U305 and related circuitry) is working correctly, there should be a 2-MHz ECL signal at U305 pin 14. The programming to the rate multiplier (128-, 64-, 32-, 16-, and 8-MHz bits) is active low. There are 20 steps in the rate multiplier programming. The logic states for the N-divider are given in Table 6C-5.
10. If the N-divider is functional, check the mixer amplifier Q205 and Q206.
11. Check the collector bias at C273 for approximately 8V.
12. Check for a 40-MHz 1.2V p-p signal at TP5.
13. Check the output of the filter, TP11, for a 500-mV p-p slightly triangular signal. The frequency is below 125 kHz, and its exact value is a function of how close the programmed RF output signal is to 640 MHz.
14. Re-enable the search oscillator by removing the ground from TP28-TP13 and grounding TP11. There should be a 100 Hz 10V p-p sine wave ( $\sim 0$ V dc) at TP6.
15. Program the UUT to SPCL 943. This programs the dac's to full scale, which turns Q201 through Q204 on. There should be a 100-Hz 650 mV p-p sine wave at TP7.
16. Clear the UUT. Remove the jumper between TP7 and ground. The loop should be locked. If the loop still does not lock, ground TP9. If the loop locks, the problem is in the delay line discriminator section. If the loop is locked and status code 243 is still present, check the unlock detector, U204.

If the phase noise of the UUT is beyond specified limits, the problem could be in the discriminator section. Check it as follows:

1. Measure the dc voltage at TP1 on the A25 Discriminator PCA. It should be  $\pm 200$  mV as the RF frequency is changed.
2. If the voltage is nearly zero, remove the semi-rigid cable connected to J10, and measure the power with the spectrum analyzer. The power should be between +9 and +14 dBm depending on the frequency.

Table 6C-5. N-Divider Logic States

FRONT PANEL FREQUENCY (MHz)	COARSE LOOP FREQUENCY (MHz)	LOGIC STATE						
		CF1	CF0	128	64	32	16	8
15.00	576	0	0	1	0	0	1	1
15.25	584	0	0	1	0	0	1	0
15.50	592	0	0	1	0	0	0	1
15.75	600	0	0	1	0	0	0	0

648	744	0	1	1	0	0	1	0
656	752	0	1	1	0	0	0	1
664	760	0	1	1	0	0	0	0
672	768	0	1	0	1	1	1	1
680	776	0	1	0	1	1	1	0
688	784	0	1	0	1	1	0	1
696	792	0	1	0	1	1	0	0
704	800	1	0	1	1	1	1	1
896	808	1	0	1	1	1	1	0
904	816	1	0	1	1	1	0	1
912	824	1	0	1	1	1	0	0
920	832	1	0	1	1	0	1	1
928	840	1	0	1	1	0	1	0
936	848	1	0	1	1	0	0	1
944	856	1	0	1	1	0	0	0
952	864	1	1	1	0	1	1	1
960	872	1	0	1	0	1	1	0
968	880	1	0	1	0	1	0	1
976	888	1	0	1	0	1	0	0
984	896	1	0	1	0	0	1	1
992	904	1	0	1	0	0	1	0
1000	912	1	0	1	0	0	0	1
1008	920	1	0	1	0	0	0	0
1016	928	1	0	0	1	1	1	1
1024	936	1	0	0	1	1	1	0
1032	944	1	0	0	1	1	0	1
1040	952	1	0	0	1	1	0	0
1048	960	1	1	1	1	1	1	1

3. If there is no power or if the power is low, use the spectrum analyzer with 500Ω 10X probe to compare the RF power amplifier levels at Q404 and Q405 with those listed in Table 6C-6. The actual levels are 20 dB higher. The levels in Table 6C-6 are approximate and can vary as much as ±3 dB.

Table 6C-6. Discriminator RF Section Levels

FRONT PANEL FREQUENCY	COARSE LOOP FREQUENCY	Q404-C	Q405-C	C421	A25-J9
544 MHz	640 MHz	-9 dBm	+3 dBm	+3 dBm	+3 dBm
704 MHz	800 MHz	-11 dBm	-3 dBm	0 dBm	-6 dBm
1048 MHz	960 MHz	-9 dBm	-2 dBm	-2 dBm	-5 dBm

4. The Q404 and Q405 collector bias voltages should be 10.4V and 5.1V.
5. If the power is correct at the collector of Q405 but low at C421, the problem is probably in the switched low-pass filter. If the power is correct at C421 but low at the cable connecting to J10, the problem is probably in the coupler or delay line. If the power is correct at the output of the delay line and the dc voltage at the output of the mixer is nearly zero, the problem is probably a defective mixer. Problems with the delay line assembly necessitate replacing the whole assembly, including the cable.

To check the discriminator amplifier, which consists of Q101 through Q105, proceed as follows:

1. Remove the end of the resistor that connects to J3 on the A25 Discriminator PCA.
2. Connect the resistor to the UUT front panel MOD OUTPUT.
3. Program the UUT to MOD FREQ 1 kHz and MOD LEVEL 4 mV. There should be a 500-mV p-p 1 kHz signal at TP9.

### COARSE LOOP PCA ADJUSTMENTS

6C-25.

Refer to Table 6C-7 for information about the test points for the A2 Coarse Loop PCA. The following procedures cover the five adjustments on the A2 Coarse Loop PCA:

- R102, Discriminator video amplifier offset
- R221, Steering gain adjustment
- R227, Acquisition oscillator level adjustment
- L601, 40-MHz oscillator adjustment
- L612 and L613, 80-MHz filter tuning
- R617, 80-MHz level adjustment
- L205, 2-MHz notch adjustment
- SW502, Alternate reference frequency selection

Table 6C-7. A2 Coarse Loop PCA Test Points

TEST POINT	SIGNAL TYPE	RANGE	TYPICAL	SIGNAL DESCRIPTION
TP1	ECL	40 MHz	800 mV p-p	N-divider Output
TP2	ECL	0 to 16 MHz	2 MHz 25 ns AH	Rate Multiplier Output
TP3	RF-ECL	120 to 240 MHz	162 MHz,+5 dBm*	Divide-by-4 Prescaler Output
TP4	ac	40 MHz	1V p-p	40-MHz Oscillator Output
TP5	ac	40 MHz	1.2V p-p	40-MHz Reference Amplifier Output
TP6	dc	+/-1V	Varies	Loop Amplifier/Acquisition Oscillator Output
TP7	dc	+/-0.1V	Varies	VCO Phase-Lock Port
TP8	dc	2 to 22V	11V	VCO Steering Port
TP9	dc	+/-50 mV	Varies	Discriminator Loop Amplifier Output
TP10				Input for Test
TP11	dc	+/-50 mV	Varies	Low-Pass Filter Output
TP12	Ground			
TP13	Shorting Connection	-	-	Disables Acquisition Oscillator
TP14	Ground	-	-	-
TP15	TTL	10 MHz	150 ns AL	Reference Loop Phase Detector Output
TP16	ac	20 MHz	1V p-p	20-MHz Reference to Modulation Oscillator
TP17	ac	40 MHz	800 mV p-p	40-MHz Reference to Subsynthesizer
TP18	dc	12.7 +/-0.2V	Constant	On when internal TXCO
		0.8 +/-0.2V	Constant	Off when external or high/medium stability option
TP19	dc	1 to 11V	5.6V	Reference Loop Amplifier Output
TP20	Shorting Connection	-	-	Opens reference loop for troubleshooting

\* As measured with 500Ω 10X RF probe (TEK 6156). Actual level as displayed on spectrum analyzer will be approximately 20 dB lower.

**NOTE**

*These adjustments are not routine and are required only when you replace the associated components or when the adjustment has been changed or has shifted. An exception is SW502, the alternate reference frequency selection, which you may need to change whenever required by your external reference applications.*

**Discriminator Video Amplifier Offset Adjustment, R102**

**6C-26.**

**TEST EQUIPMENT:**

- DVM

**REMARKS:**

Discriminator video amplifier offset adjustment is normally required only when Q102 or any associated components have been replaced or when the adjustment has shifted.

**PROCEDURE:**

The output of the discriminator video amplifier (TP9) is adjusted to 0V dc.

1. Program the UUT to SPCL 909.
2. Connect the dvm to measure voltage between TP9 and ground.
3. Adjust R102 for  $0V \pm 10 \text{ mV}$ .

**Steering Gain Adjustment, R221**

**6C-27.**

**TEST EQUIPMENT:**

- DVM

**REMARKS:**

The steering gain adjustment is normally required only when U207 or any associated components have been replaced or when the adjustment has shifted.

**PROCEDURE:**

The Coarse Loop VCO steering voltage is adjusted to 24V with the Coarse Loop VCO steering dac set to full scale.

1. Program the UUT to SPCL 909.
2. Program the UUT to SPCL 943. This Special Function programs all dac's to full scale.
3. Connect the dvm to measure the voltage between TP8 and ground (TP14).
4. Adjust R221 for  $24.00V \pm .01V$ .
5. Program the UUT for SPCL 00. This clears all Special Functions.

**Acquisition Oscillator Level Adjustment, R227**

**6C-28.**

**TEST EQUIPMENT:**

- DVM

**REMARKS:**

The acquisition oscillator level adjustment is normally required only when U206 or any associated components have been replaced, or when the adjustment has shifted.

**PROCEDURE:**

Acquisition oscillator level at TP6 is adjusted for 3.54V rms with the phase-locked loop disabled.

1. Connect TP11 to ground (TP13) with a clip lead.
2. Connect the DVM to measure the ac voltage between TP6 and ground.
3. Adjust R227 for 3.54V rms  $\pm 0.10$ V.

**40-MHz Oscillator Adjustment, L601****6C-29.****TEST Equipment:**

- Frequency counter
- DVM

**REMARKS:**

The 40-MHz oscillator adjustment is normally required only when Q606 or any associated components have been replaced or when the adjustment has shifted.

**PROCEDURE:**

The 40-MHz oscillator is adjusted to 40 MHz with the crystal removed from the circuit.

1. Program the UUT to SPCL 909, and select internal reference.
2. Connect counter external reference OUT to UUT 10 MHz IN. Set UUT to EXT REF.
3. Move the jumper from TP22-TP24 to TP22-TP23, and move the jumper from TP26-TP27 to TP25-TP26. This removes the crystal from the circuit.
4. Connect the frequency counter to TP4. Set for 1-kHz resolution.
5. Adjust L601 for 40 MHz  $\pm 10$  kHz.
6. Replace the jumpers to original positions.
7. Set the frequency counter for 1-Hz resolution. Verify the frequency is 40 MHz  $\pm 1$  count on the frequency counter.
8. Measure voltage at TP19. It should be between 4.5 and 7.5V dc.

**80-MHz Filter Tuning, L612 and L613**

**6C-30.**

**TEST EQUIPMENT:**

- Spectrum analyzer

**REMARKS:**

Tuning the 80-MHz filter is normally required only when components in the doubler section, Q609, Q610 and related components, have been replaced, or when the adjustment has shifted.

**PROCEDURE:**

The 80-MHz output from the coarse loop is adjusted for the maximum level.

1. Program the UUT to SPCL 909.
2. Remove the cable and connect the spectrum analyzer to A2-J5. Set the spectrum analyzer to 80 MHz, 1-MHz span, and 10-dBM reference level.
3. Adjust L612 for the maximum level.
4. Adjust L613 for the maximum level.
5. Repeat steps 3 and 4 until the level no longer increases.
6. Reinstall the cable.

**80-MHz Level Adjustment, R617**

**6C-31.**

**TEST EQUIPMENT:**

- Spectrum analyzer

**REMARKS:**

The 80-MHz level adjustment is normally required only when Q606, Q609, Q610, U601 and associated components have been replaced, or when the adjustment has been changed or has shifted. This adjustment should be done after L612 and L613 have been adjusted.

**PROCEDURE:**

The 80-MHz level from A2-J5 is adjusted to 4 dBm.

1. Program UUT to SPCL 909.
2. Remove the cable from A2-J15. Connect A2-J15 to the spectrum analyzer. Set the spectrum analyzer to 80 MHz, 1 MHz-span and 10-dBm reference level.
3. Adjust R617 for 4 dBm  $\pm$ 0.2.
4. Reconnect the cable to A2-J15.

**2-MHz Notch Adjustment, L205**

**6C-32.**

**TEST EQUIPMENT:**

- Spectrum analyzer

**REMARKS:**

The 2-MHz notch adjustment is normally required only if L205 and associated components have been replaced or when the adjustment has shifted.

**PROCEDURE:**

The 2-MHz signal at the output of the acquisition oscillator is minimized.

1. Program the UUT to SPCL 909.
2. Program the UUT to 15.25 MHz.
3. Connect the spectrum analyzer to TP6 with clip leads. Set the spectrum analyzer to center 2 MHz, 100-kHz span, and ref level -20 dB.
4. As L205 is adjusted inward, a signal should become visible on the spectrum analyzer. Adjust L205 to minimize this signal.

**Alternate Reference Frequency Selection**

**6C-33.**

**REMARKS:**

The unit is configured at the factory to accept a 5-MHz external reference when the unit is in alternate reference frequency mode, SPCL 761. You can change the alternate reference from 5 MHz to 1 or 2 MHz by changing the position of switch SW502.

**PROCEDURE:**

1. On the synthesizer module bottom cover, remove the metal hole plug labeled A2S502.
2. Set the switches as shown in Table 6C-8.

Table 6C-8. Setting SW502 for Alternate Reference Frequency

REFERENCE FREQUENCY	SW502 Switch Segments					
	1	2	3	4	5	6
5 MHz	ON	ON	OFF	OFF	ON	OFF
2 MHz	OFF	OFF	ON	ON	OFF	OFF
1 MHz	OFF	ON	OFF	ON	OFF	ON

**A5 COARSE LOOP VCO CIRCUIT DESCRIPTION**

**6C-34.**

The A5 Coarse Loop VCO PCA is controlled by the A2 Coarse Loop PCA and produces a signal that is further processed in the A12 Sum Loop PCA. This assembly includes three varactor-tuned oscillator circuits that cover the frequency range 576 to 960 MHz, programmed by binary control signals CSVCO0H and CSVCO1H, as listed in Table 6C-9.

Table 6C-9. Coarse Loop VCO Binary Band Control Signals

BAND	FREQUENCY RANGE (MHz)	CSVCO0H	CSVCO1H
1	576 to 704	0	0
2	712 to 824	0	1
3	832 to 968	1	1

The three oscillator circuits are designed similarly but have different element values and printed transmission line lengths to cover the three bands. Because the three circuits operate the same, the following discussion specifies only the reference designators for the band 1 oscillator. Refer to the A5 Coarse Loop VCO schematic diagram in Section 10 to locate corresponding elements for the other two oscillators. (Components for each band are identified on the schematic.)

Band 1 oscillator uses a common-base transistor, Q3, configured for negative resistance at the emitter. The emitter is coupled to a resonator that consists of a printed transmission line in series with varactor diodes CR5 and CR6, and low loss porcelain capacitors C5 and C6. Two tuning voltage lines connect to the varactor cathodes and anodes via RF chokes L6 and L3, respectively. The cathodes connect to the vco steering port, J6. The anodes connect to the vco phase lock port, J5. These ports are used by the A2 Coarse Loop PCA to control the operating frequency. The voltage across the varactors, measured between J6 and J5, varies approximately linearly with frequency in each band, from about 2V to 20V.

The +13 dBm nominal signal at the oscillator transistor collector is applied to an 8-dB attenuator R13 through R15 that provides isolation, and then to a low-pass filter consisting of C41, C42, and printed lines that attenuates harmonics to less than -20 dBc. PIN diode CR9 has low RF resistance and passes the oscillator signal when the oscillator is on and goes to a high impedance when the oscillator is off.

Band control signals CSVCO0H and CSVCO1H are decoded by U3 and Q4 through Q8. This circuit applies bias current only to the selected oscillator transistor so that only one oscillator is activated per band.

PIN diodes CR7 through CR9 connect the active oscillator to a resistive signal splitter, R21 and R22, which drives monolithic 11 dB amplifiers U1 and U2. The +7 dBm output of U1 connects to the A2 Coarse Loop PCA at J7 by a through-the-plate coaxial connector, and the output of U2, also at +7 dBm, connects to the A12 Sum Loop PCA at J8 by a coaxial cable.

**COARSE LOOP VCO TROUBLESHOOTING**

**6C-35.**

The Coarse Loop VCO PCA, controlled by the Coarse Loop PCA, generates the coarse loop signal that is further processed in the A12 Sum Loop PCA. A problem with the Coarse Loop VCO can cause Coarse Loop Unlock status code 243 to appear. Self-test error codes 320 through 323 can also be triggered by a failed A9 Sum Loop VCO. To determine if a failure is due to the Coarse Loop VCO rather than another assembly, perform the following tests:

1. Ground J5, the phase-lock port of the vco with a clip lead and measure the dc voltage at J6 with the UUT programmed to SPCL 943 (all dac's to full scale). The reading should be 24.00V.
2. Program the UUT to SPCL 942 (all dac's to half scale). The reading should be 12.00V. This tests the vco steering voltage circuit.
3. With J5 still grounded, examine the output at connector J8 with a spectrum analyzer as the frequency is stepped in 8 MHz increments from 512 MHz to 1056 MHz. The frequency should always be within about 2 MHz of expected coarse loop frequency, and the level should be approximately +5 dBm. (The expected coarse-loop frequency can be displayed by entering SPCL 946.) If the signal is good, the problem is likely in another PCA. If the signal is incorrect only over a frequency band corresponding to one of the vco bands, the associated vco circuit is likely at fault.
4. Measure dc voltages at various circuit nodes with the UUT programmed to 600 MHz, 700 MHz, and 1000 MHz to enable each of the three bands. Compare your readings with Table 6C-10. These measurements should help isolate the problem circuit.

**SUM LOOP BLOCK DIAGRAM**

**6C-36.**

Refer to the Sum Loop Block Diagram (see Figure 6C-8) to identify major functional sections and to follow the signal paths of the sum loop.

Table 6C-10. A5 Coarse Loop VCO PCA Expected DC Voltages

LOCATION	VOLTS DC
ON bias transistor collector (Q4, Q5, or Q6, depends on band)	-14.3
OFF bias transistor collectors	0
ON oscillator transistor collector (Q1, Q2 or Q3, depends on band)	+8.3
OFF oscillator transistor collectors	+9.6
U1, U2 outputs	+4.4
CR7, CR8, CR9 node	+9.9

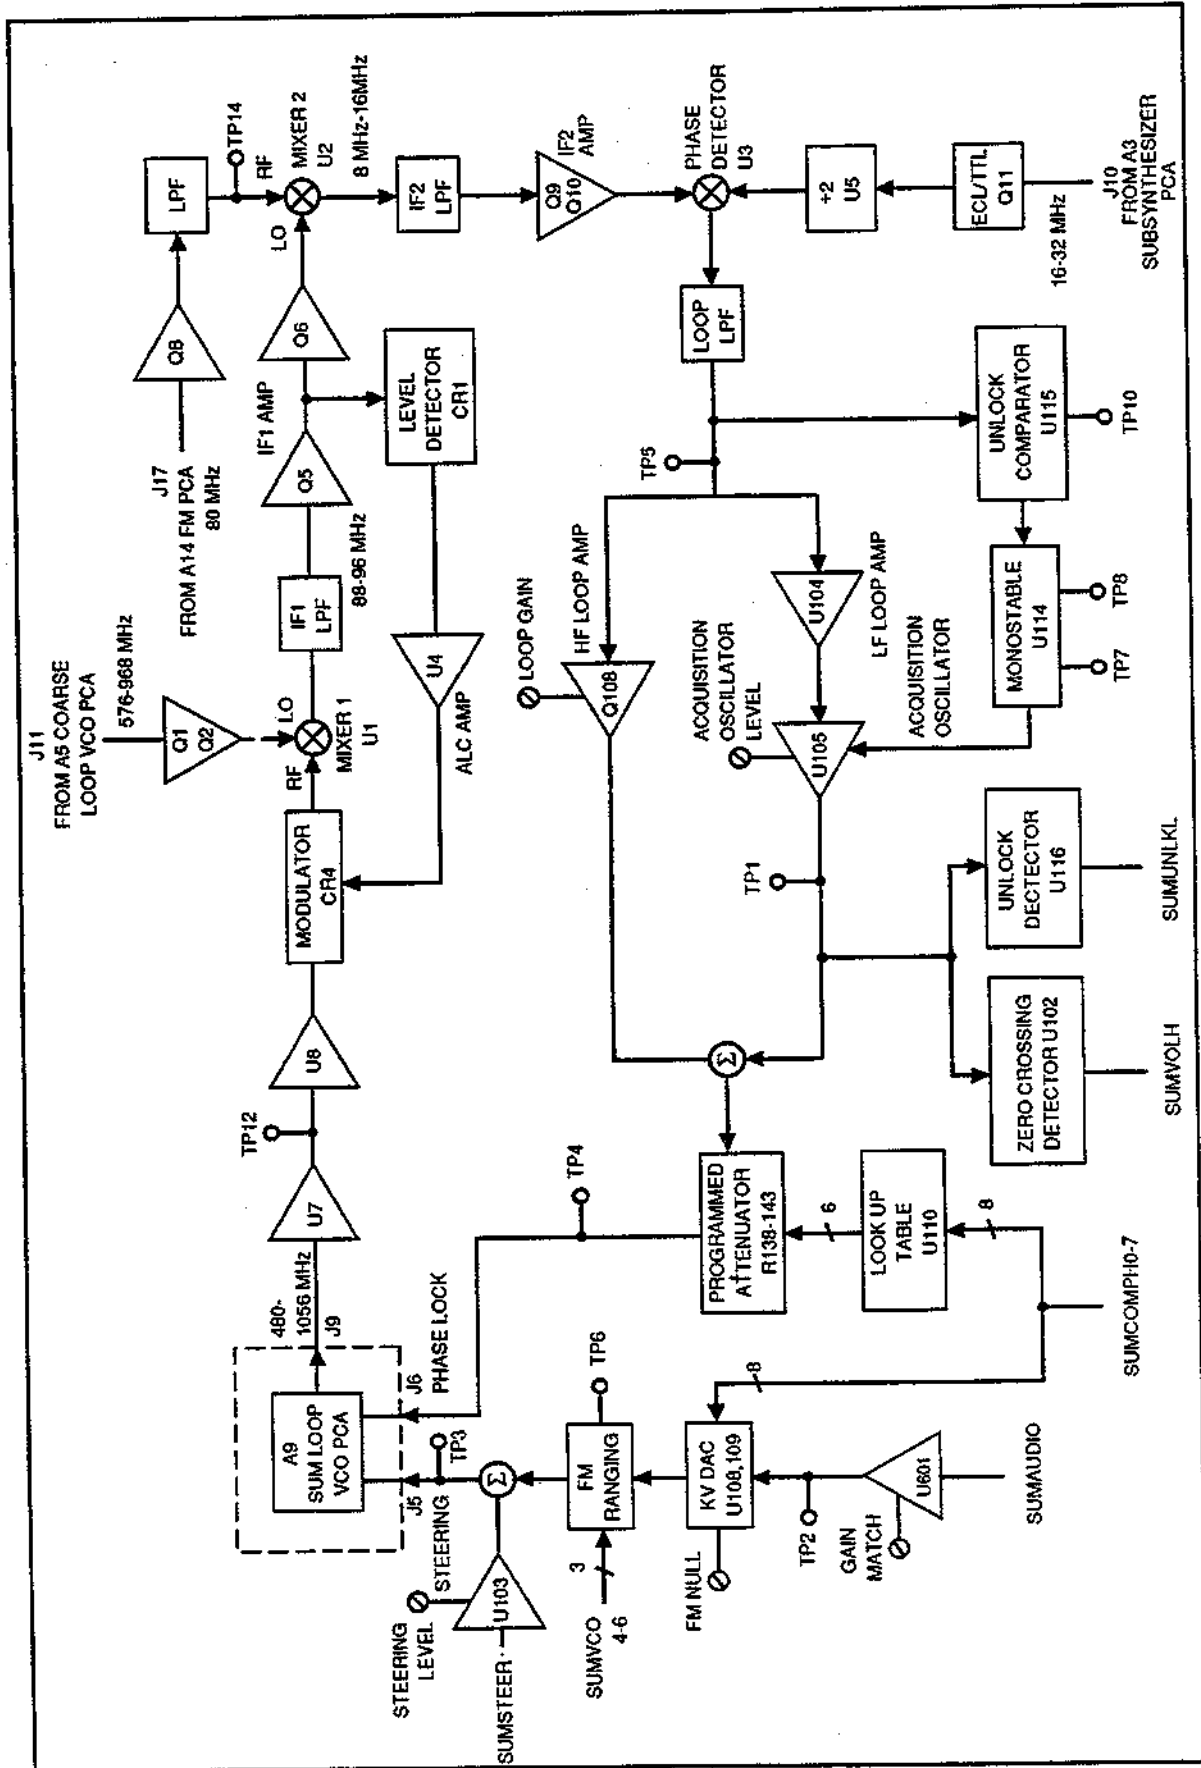

Figure 6C-8. Sum Loop Block Diagram

**A12 SUM LOOP CIRCUIT DESCRIPTION**

**6C-37.**

The A12 Sum Loop PCA generates the fundamental frequency band, 480 to 1056 MHz, by combining signal frequencies from the FM, the Subsynthesizer, and the Coarse Loop PCAs. The sum loop was designed for spurious Signal Generation of less than -100 dBc, and for low phase noise contribution. The relation between sum loop output frequency and the input frequencies follows.

For  $f(\text{sum}) < 760 \text{ MHz}$ :

$$f(\text{sum}) = f(\text{coarse}) - f(\text{fm}) - f(\text{subsynth})$$

For  $f(\text{sum}) \geq 760 \text{ MHz}$ :

$$f(\text{sum}) = f(\text{coarse}) + f(\text{fm}) + f(\text{subsynth})$$

The A12 Sum Loop PCA includes a phase-locked loop (PLL) circuit that steers the frequency of the A9 Sum Loop VCO PCA to the correct value, according to the above equations. The loop includes an RF section (with two stages of heterodyne frequency downconversion), a phase detector circuit, and an audio section. The audio section contains the loop amplifier, acquisition circuits, and vco coarse steering circuits. The following paragraphs discuss these PLL sections.

The output signal from the A9 Sum Loop VCO PCA is coupled into the output section where the signal is further processed to generate the instrument RF OUTPUT signal.

**RF Section**

**6C-38.**

The RF section contains the RF amplifiers, mixers, and filters required to process the Sum Loop VCO signal through three successive stages of frequency downconversion. The first stage subtracts the coarse loop frequency from the Sum Loop VCO frequency to generate a first IF signal, referred to as the IF1 signal. The second stage subtracts the FM PCA signal from the IF1 signal to generate a second signal, IF2. The third stage includes a mixer phase detector that compares the IF2 signal to the subsynthesizer signal and generates the audio frequency phase-locked signal that is further processed in the audio section.

Frequency ranges for these signals are given in Table 6C-11. Note that when FM is on, the programmed deviation appears in the Sum Loop VCO signal, the IF1 signal, and the FM PCA signal.

Table 6C-11. Sum Loop Frequencies

SIGNAL	FREQUENCY RANGE (MHz)
Sum Loop VCO	480 to 1056
Coarse Loop	576 to 960
IF1	88 to 96
FM PCA	80
IF2	8 to 16
Subsynthesizer	8 to 16

The Sum Loop VCO signal at J9 is applied to buffer amplifiers U7 and U8. PIN diode CR4 follows U8 and acts as an adjustable attenuator to control the level at the RF port of double balanced mixer U1. A low-pass filter including C81 and C82 precedes U1 RF port and attenuates high order harmonics in the RF signal. The LO port of U1 is driven by a two-stage amplifier that includes Q1 and Q2. This amplifier accepts the +7 dBm signal from the Coarse Loop VCO at J11 and produces +20 dBm of drive power at the LO port of U1.

U1 generates the IF1 signal at the IF port. This signal is filtered by a 10-element, 100-MHz low-pass filter with input at L3 and output at C27. The filter is located within a channel in an aluminum cover piece to improve high frequency attenuation. This cover also shields the IF1 amplifiers and the IF2 low-pass filter.

The -14 dBm IF1 signal at the filter output is amplified by Q5, configured for 21-dB gain. Q5 drives level detector diode CR1 at +7 dBm. CR1, U4 and associated components form a level control loop that holds RF level constant at CR1 by adjusting modulator PIN diode CR4 bias current. This action also holds the signal level at U1 RF port to a constant value. Accurate RF port level control is necessary to control mixer intermod spurs and noise floor.

The leveled IF1 signal at CR1 is next applied to a 6-dB attenuator (R25-R27) and then to Q6, which is configured as a 20-dB amplifier. Q6 drives the LO port of double balanced mixer U2 with about +20 dBm. The 80-MHz signal from the A14 FM PCA is applied to the RF port of U2 and coupled via a capacitor at J17. Q8 and associated components buffer and low-pass filter this signal, which is then applied to U2 at a -8 dBm level.

U2 generates the IF2 signal at the IF port. This signal is filtered by a nine-element, 20-MHz low-pass filter with input at L9 and output at L23. Like the IF1 filter, this filter is located within a channel in an aluminum cover piece to improve high frequency attenuation. The -14 dBm signal at the filter output drives the IF2 amplifier, which includes Q9 and Q10 and is configured for 21-dB gain. Q10 drives the RF port of mixer U3 with +7 dBm, which is used as a phase detector. The IF2 low-pass filter also provides a dc path for +15V power for the IF2 amplifier.

The A3 Subsynthesizer PCA inputs a 16- to 32-MHz signal to J10. This ECL-level signal is converted to TTL by Q11 and related circuitry. The TTL signal then drives U5, a D-type flip-flop configured to divide the input frequency in half. The resulting 8- to 16-MHz Q and Q (compliment) outputs of U5 drive the LO port of U3.

The IF output of U3 drives the loop filter, a 13-element low-pass type with input at R56 and output at L26. This filter allows audio frequency components to pass with minimum phase shift while adequately attenuating RF mixer products. The loop filter output voltage is proportional to the phase difference between the RF and LO ports of U3. This signal drives the audio section, described in the following paragraphs.

### Audio Section

6C-39.

The Audio Section contains the circuits required to acquire and maintain phase lock. Inputs to this section include the phase detector voltage, Sum Loop VCO coarse steering voltage (SUMSTEER), FM modulation signal (SUMAUDIO), FM range switching signals (SUMVCO4-6), and Sum Loop VCO Kv information (SUMCOMP0-7). Audio Section outputs include Sum Loop VCO steering port and phase-lock port voltages, and a phase-locked status indicator for the controller.

## LOOP AMPLIFIER

6C-40.

The loop amplifier consists of a low frequency path and a high frequency path connected in parallel and driven by the phase detector voltage at the loop filter output (L26). This configuration minimizes noise and phase shift at frequencies around the unity loop gain frequency of 500 kHz.

The low frequency path operates from dc to about 30 kHz, and includes op amps U104, U105, and associated components. U105 is also configured as a Wien bridge-type acquisition oscillator. When the sum loop is unlocked, U105 oscillates at either 800 Hz or 14 kHz. The oscillation depends on switching FETs Q106 and Q107, which switch capacitors C127 and C131. Potentiometer R132 sets the amplitude of oscillation. U105 stops oscillating and acts as a gain-of-3 amplifier when phase lock is obtained, due to loop dynamics.

The high frequency path operates for frequencies greater than about 30 kHz, and includes Q108 and associated components. Q108 is a low-noise, high-ft transistor configured as an emitter follower. An RC circuit sums the outputs of the two paths, with C137 and C138 providing high-pass and low-pass characteristics, respectively. R167 provides loop gain adjustment.

The summing node, at TP4, is connected to the J6 Sum Loop VCO phase-lock port, and to ground through six switchable resistors, R138-R143. These switched resistors adjust loop amplifier gain to compensate for Sum Loop VCO Kv variations. Note that Kv is the slope of the frequency vs the tuning voltage function.

The switched resistors are programmed by U110, a PROM containing a look-up table. The input to U110, SUMCOMP bits 0-7, is a binary number proportional to  $1/K_v$ . The six-bit output of U110, functionally related to the SUMCOMP number, drives the programmed resistors to compensate for Kv variation with Sum Loop VCO RF frequency.

## ACQUISITION CIRCUITS

6C-41.

The acquisition circuit includes a two-frequency acquisition oscillator, an unlock detecting comparator, a loop disabling circuit, and a dual monostable multivibrator.

When the loop is properly phase locked, the phase detector voltage at TP5 stays close to 0V, because the loop forces equal frequency and nearly equal phase for the phase detector inputs. If the loop was opened, for instance by shorting the vco phase lock port at TP4, the phase detector would generate a beat frequency triangle wave signal of about 300 mV amplitude. Thus, the presence of a voltage above a threshold level indicates loop unlock. High speed comparator U115 trips and activates a two-stage acquisition sequence when the phase detector voltage exceeds 190 mV, indicating loop unlock.

The output of U115 is applied to the 1A input of U114, a dual monostable multivibrator, and trips one-shot A upon unlock detection. One-shot A is configured for a 10-ms output pulse and drives comparators U102A and U102B, which disable the low and high frequency paths of the loop amplifier, respectively, during the 10-ms pulse. U102A turns off Q109, and U102B turns off bias current to Q108, effectively open circuiting the loop amplifier.

This disabling action of opening the loop allows time for all the frequency inputs to the Sum Loop PCA to settle to proper values following a change in instrument RF frequency, prior to sum loop phase-lock acquisition. The trailing edge of the one-shot A pulse triggers one-shot B, at the 2B input.

One-shot B is configured for a 0.5-ms pulse and drives comparator U102C, which switches acquisition oscillator U105 to the 14-kHz mode. This acquisition frequency results in optimum lock-on behavior. During the 0.5-ms pulse, unlock comparator U115 is disabled to allow acquisition to occur. If Sum Loop PCA inputs are correct, acquisition occurs during the 0.5-ms pulse, and U105 stops oscillating, due to changes in loop dynamics. After the 0.5-ms one-shot B pulse, U105 is set to the 800-Hz mode to improve closed-loop dynamics, but does not oscillate if the lock was obtained.

U102D is a zero crossing comparator that senses the polarity at TP1, the low frequency loop amplifier output, and generates the SUMVOLH signal. The controller uses this signal during the Sum Loop VCO calibration routine.

Monostable multivibrator U116 is triggered by the acquisition oscillation at U105. This occurs when the sum loop is unlocked, and generates the SUMUNLKL signal. The signal informs the controller that the sum loop is not locked.

### SUM LOOP VCO STEERING CIRCUIT

6C-42.

The Sum Loop VCO has two ports for frequency tuning: the steering port at J5 and the phase-locked port at J6. A coarse tuning voltage, generated at the steering port, tunes the Sum Loop VCO frequency to the desired value, within about  $\pm 2$  MHz. The phase-locked port is driven by the loop amplifier with enough voltage to compensate for any error in the steering port, and sets the Sum Loop VCO frequency to the correct phase-locked value. The following paragraphs describe the circuit that drives the steering port.

The SUMSTEER signal is generated in a 12-bit dac on the A33 Modulation Control PCA. The dac is programmed by data stored in the controller. Note that this data is obtained and stored during the Sum Loop VCO compensation procedure, and is unique to a given vco.

The SUMSTEER signal is input at J7-14. This signal, an RF frequency-dependent dc voltage, is proportional to the required steering port voltage. The signal is low-pass filtered and amplified by U103 and associated components. Resistor R112 adjusts the gain of the circuit. Depending on the RF frequency, the dc voltage at steering port TP3 varies from 0 to 26V.

The 80-MHz FM source for the Signal Generator is output by the A14 FM PCA. The Sum Loop VCO is phase locked to this 80-MHz input signal, and any frequency modulation on the signal is transferred to the Sum Loop VCO. However, at high levels of FM deviation, the required voltage swing at the vco phase-lock port would require a phase detector output greater than possible, and thus the sum loop would lose lock.

This problem is avoided by applying an ac signal at the vco steering port that provides nearly the correct deviation in the Sum Loop VCO during high deviation FM operation. Thus, the loop must generate only a small error voltage at the vco phase-lock port to maintain lock, and the phase detector output stays acceptably small.

The SUMAUDIO signal at J8-1, from the A14 FM PCA, is an ac frequency-modulating signal with amplitude proportional to FM deviation. This signal is buffered by op amp U106, which is configured for unity gain. The signal can be switched via U107 for inverting or non-inverting operation. These two modes are required to properly phase the cancellation signal, depending on fundamental frequency band. For  $f(\text{fund}) < 760 \text{ MHz}$ , U106 inverts, while for  $f(\text{fund}) \geq 760 \text{ MHz}$ , U106 is non-inverting. R121 provides gain equalization for the two modes.

The buffered signal at TP2 is next applied to dac U109, which is programmed by SUMCOMP bits 0-7. These eight bits encode a number proportional to Sum Loop VCO  $1/K_v$ . Note that  $K_v$  is the slope of the frequency vs the tuning voltage function. Thus, dac U109 scales the signal to account for vco tuning voltage sensitivity variations with RF frequency. R116 adjusts the gain for dac U109.

The dac output at U108 pin 6 is next applied to a switched RC network, which includes R105-108 and related components. The switched RC network is programmed by fm range-switching bits SUMVCO4-6 depending on FM deviation range. This network scales the signal to the appropriate level. The vco steering port TP3, outputs the desired ac cancellation signal. Noise contribution at the vco steering port is reduced by C105, which is switched to ground by Q101 when the cancellation circuit is not active.

## SUM LOOP TROUBLESHOOTING

6C-43.

Since the primary function of the sum loop is to combine various signal frequencies into the desired fundamental band frequency, sum loop problems generally cause frequency errors at the UUT output. To troubleshoot, check for sum loop fault status codes 244 and 245. The implications of these errors and suggested troubleshooting sequences in response to the codes are described below. To aid in understanding these circuits, read the detailed circuit descriptions for the A12 Sum Loop and A9 Sum Loop VCO assemblies earlier in this section before you troubleshoot.

Status code 244 indicates that the sum loop is not properly phase locked, and is triggered by the free-running loop acquisition oscillator. This fault can be caused by a problem with the input signals to the sum loop, or by a problem in the A12 Sum Loop PCA or the A9 Sum Loop VCO PCA. The sum loop can be unlocked by a faulty input signal from the Coarse Loop, the Subsynthesizer, or the FM assembly.

To begin troubleshooting sum loop problems, proceed as follows:

1. Check for fault status codes that indicate incorrect operation of the Subsynthesizer PCA, the Coarse Loop PCA, and the FM PCA. Repair any indicated assemblies and recheck for Status Code 244.
2. If the code still appears, check that the three input signals listed in Table 6C-12 are the correct frequency and level. Measure the FM signal using a  $500\Omega$  probe with the spectrum analyzer. Detach the coarse loop and subsynthesizer cables from the Sum Loop PCA and connect them directly to the spectrum analyzer. Display the coarse loop and subsynthesizer frequencies by entering SPCL 946 and SPCL 947, respectively, for any UUT frequency.

If the signals in Table 6C-12 are the correct frequency and level, first verify that the Sum Loop VCO is functional as follows:

## FREQUENCY SYNTHESIS

Table 6C-12. Preliminary Sum Loop Troubleshooting Checks

SIGNAL DESCRIPTION	TEST LOCATION	FREQUENCY	LEVEL
Coarse Loop	Cable W14	Use SPCL 946	+7 dBm
FM	TP14	80 MHz	-13 dBm
Subsynthesizer	Cable W13	See equations below or use SPCL 947	+3 dBm
For $f(\text{sum}) < 760$ MHz, $f$ in MHz: $f(\text{subsynth}) = 2 * (f(\text{coarse}) - 80 - f(\text{sum}))$ For $f(\text{sum}) \geq 760$ MHz, $f$ in MHz: $f(\text{subsynth}) = 2 * (f(\text{sum}) - 80 - f(\text{coarse}))$			

1. Ground TP4, the phase-lock port, and measure the Sum Loop VCO signal at TP12 using a 500Ω probe with a spectrum analyzer.
2. The measured frequency should be within 2 MHz of the expected sum loop frequency. If the signal is absent or is far off frequency, either the Sum Loop VCO or the vco steering voltage circuit is faulty.
3. Check the steering voltage circuit by programming the UUT with SPCL 943. Measure the dc voltage at TP3, the vco steering port. This special function programs the steering dac to full scale and should result in a reading of 26.00V. If the Sum Loop VCO is functioning properly, troubleshoot the Sum Loop PCA.

Proceed as follows to troubleshoot the Sum Loop PCA:

1. Keep the phase-lock port TP4 shorted to ground and measure the signal at the phase detector output, TP5, with an oscilloscope.
2. This signal should be a 0.56V p-p triangle wave with a frequency of less than 2 MHz. An incorrect signal indicates a fault in the phase detector or the RF circuitry preceding it.
3. Check the RF circuits to isolate a problem by measuring signal levels and frequencies at various points with a 500Ω probe and a spectrum analyzer. Table 6C-13 lists expected frequencies and approximate levels in a suggested test sequence, and Table 6C-14 contains dc bias voltage information for circuits in the RF section. When checking signal levels, short TP4 to ground, and ground the 500Ω probe as closely as possible to each test point. The PCA hold-down screws and the walls of the plate provide good grounds.

An appropriate signal at TP5, with TP4 shorted to ground, indicates a problem in the audio section rather than in the RF circuits. To check the loop amplifier/ acquisition oscillator, proceed as follows:

1. Short TP5 to ground and measure the waveform at TP1 with an oscilloscope. The waveform at TP1 should be about a 800 Hz, 14V p-p sine wave.
2. With both TP5 and TP8 shorted to ground, measure the TP1 waveform for an approximate 13.6 kHz, 8V p-p sine wave. Failure of this test indicates a problem somewhere between TP5 and TP1.

Table 6C-13. A12 Sum Loop PCA RF Circuitry Test Information

LOCATION	CIRCUIT	FREQUENCY	LEVEL**
J11	U1 LO amplifier	f(coarse)	-14 dBm
Q2 collector	U1 LO amplifier	f(coarse)	-1 dBm
J9	U1 RF amplifier	f(sum) +/-2 MHz	-34 dBm
TP12	U1 RF amplifier	f(sum) +/-2 MHz	-24 dBm
Q5 base	IF1 amplifier	f(IF1)*	-35 dBm
R25/R26 node	IF1 amplifier	f(IF1)*	-15 dBm
Q6 collector	IF1 amplifier	f(IF1)*	-5 dBm
R17/R45 node	FM amplifier	80 MHz	-26 dBm
TP14	FM amplifier	80 MHz	-13 dBm
Q9 base	IF2 amplifier	f(sub-syn)/2 +/-2 MHz	-37 dBm
Q10 collector	IF2 amplifier	f(sub-syn)/2 +/-2 MHz	-18 dBm
J10	ECL/TTL buffer	f(sub-synth)	-18 dBm
R57/C60 node	U3 LO driver	f(sub-synth)/2	-26 dBm

\* f(IF1) = (f(sub-synth)/2 + 80) +/-2 MHz  
 \*\* Levels are approximate and are measured using a 500Ω probe with a spectrum analyzer.

Table 6C-14. A12 Sum Loop PCA RF Section DC Bias Voltages

LOCATION	CIRCUIT	VOLTS DC
Q1 collector	U1 LO amplifier	+9.8
Q2 collector	U1 LO amplifier	+4.9
U7 output	U1 RF amplifier	+4.7
U8 output	U1 RF amplifier	+4.7
Q5 collector	IF1 amplifier	+9.5
Q6 collector	IF1 amplifier	+3.5
Q8 collector	FM amplifier	+9.8
Q9 collector	IF2 amplifier	+6.4
Q10 collector	IF2 amplifier	+8.5
Q11 collector	ECL/TTL buffer	+1.0

To check the programmable attenuator for proper operation, proceed as follows:

1. Connect TP7 and TP9 to ground.
2. Program the UUT to SPCL 943 (dac's set to full scale), and measure the resistance from TP4 to ground for a reading of about 240Ω.
3. Program the UUT to SPCL 941 (dac's set to zero) for a resistance reading of about 29.5Ω. Failure of this test indicates a problem somewhere between TP1 and TP4.

## FREQUENCY SYNTHESIS

Status Code 245 indicates an unlevelled condition in the leveling loop that controls the signal amplitude at the RF input of mixer U1. A fault code displays when the modulator control voltage at J16 exceeds about 10V. This fault condition can be caused by either a level problem in the RF path (including the Sum Loop VCO and sum loop circuits between J9 and CR1), or by improper signal frequencies within the sum loop.

Table 6C-15 presents the nominal characteristics of the signals at the various test points on the A12 Sum Loop PCA. This table lists the normal range of the signals, along with specific values for the instrument diagnostic state.

Table 6C-15. A12 Sum Loop PCA Test Points

TEST POINT	SIGNAL TYPE	RANGE	TYPICAL FOR SPCL 909	SIGNAL DESCRIPTION
TP1	dc+audio	+/-4V	0V	Loop amp low frequency output
TP2	audio	0 to 3.0V rms	0V	SUMAUDIO buffer amplifier output
TP3	dc+audio	0 to 26.0V	15V	Sum Loop VCO steering voltage
TP4	dc+audio	+/-8V	0V	Sum Loop VCO phase lock voltage
TP5	dc+audio	+/-150 mV	0V	Phase detector voltage
TP6	N/A	This test point is an input for sum loop test and alignment.		
TP7	TTL	TTL high, low	TTL high	Loop disabling one-shot output signal
TP8	TTL	TTL high, low	TTL high	Acquisition oscillator switching signal
TP9	dc+audio	+/-4V	0V	Filtered loop amp LF output
TP10	N/A	This test point is shorted to ground for sum loop test and alignment.		
TP11	N/A	This test point is shorted to ground for sum loop test and alignment.		
TP12	RF*	-20 to -28 dBm 480-1056 MHz	-24 dBm 600 MHz	Buffered Sum Loop VCO signal
TP14	RF*	-13 dBm 80 MHz	-13 dBm 80 MHz	Buffered FM oscillator signal
TP15	ground			

\* RF Levels are approximate and are measured using a 500Ω probe with a spectrum analyzer.

### SUM LOOP ASSEMBLY ADJUSTMENTS

6C-44.

The following procedures cover the five potentiometer adjustments on the A12 Sum Loop PCA listed below:

- R112, Steering level adjustment
- R121, Buffer gain match adjustment
- R116, FM null adjustment
- R167, Loop gain adjustment
- R132, Acquisition oscillator level adjustment

**NOTE**

*These adjustments are not routine and are required only when you replace the associated components or when you change the adjustment.*

**Steering Level Adjustment, R112****6C-45.****TEST EQUIPMENT:**

- DVM

**REMARKS:**

The Steering Level Adjustment is normally required only when U103 or any associated components have been replaced or when the adjustment has shifted.

**PROCEDURE:**

Adjust the Sum Loop VCO steering voltage to +26V dc with the Sum Loop VCO steering dac set to full scale.

1. Program the UUT to SPCL 909.
2. Program the UUT to SPCL 943 to program all dac's to full scale.
3. Connect the dvm to measure the voltage between TP3 and TP15 (ground).
4. Adjust R112 for +26.00V  $\pm$ .02V.
5. Program the UUT for SPCL 00. This clears all Special Functions.

**Buffer Gain Match Adjustment, R121****6C-46.****TEST EQUIPMENT:**

- DVM

**REMARKS:**

The buffer gain match adjustment is normally required only when U106 or any associated components have been replaced or when the adjustment has shifted.

**PROCEDURE:**

Adjust the SUMAUDIO buffer amplifier for equal gain in the inverting and non-inverting modes.

1. Program the UUT to SPCL 909, 800 MHz, 4 MHz FM deviation, and 1 kHz mod frequency. Turn INT FM on.
2. Connect the dvm to measure the ac voltage between TP2 and TP15 (ground).
3. Note the dvm reading.

4. Program the UUT to 700 MHz.
5. Adjust R121 for a dvm reading equal to that noted in step 3,  $\pm 5$  mV.

**FM Null Adjustment, R116**

**6C-47.**

**TEST EQUIPMENT:**

- Oscilloscope

**REMARKS:**

Perform the FM null adjustment under the following conditions:

- If the A12 Sum Loop PCA has been replaced or the A14 FM PCA has been replaced or repaired.
- If U108, U109, or any associated components have been replaced or the adjustment has been changed or has shifted.

**PROCEDURE:**

With the UUT programmed for INT FM on, and 4-MHz FM deviation at 168-kHz mod frequency, adjust the ac error voltage at TP5 (the phase-detector output), for a minimum peak-to-peak value.

1. Program the UUT to SPCL 909, 700 MHz, 4-MHz deviation, and 168-kHz mod frequency. Turn INT FM on.
2. Set the oscilloscope for 50 mV/division vertical, 2 us/division horizontal, and ac coupling.
3. Connect the oscilloscope probe to monitor the signal at TP5, using TP15 for the ground connection.
4. Adjust R116 for a minimum peak-to-peak voltage. The waveform should be less than 150 mV p-p.

**Loop Gain Adjustment, R167**

**6C-48.**

**TEST EQUIPMENT:**

- High-frequency synthesized signal generator (HFSSG)
- Wideband ac voltmeter (WBVM)

**REMARKS:**

- The Loop Gain Adjustment is normally required only when U3, Q108, or any associated components are replaced or when the adjustment has shifted.
- The upper plate cover of the lower module must be installed prior to this adjustment.

**PROCEDURE:**

An 800-kHz signal is applied to the Sum Loop VCO steering port through TP6. Then adjust the loop gain via R167 until the ac voltages at the Sum Loop VCO steering and phase lock ports are equal.

1. Access R167, TP3, TP4, and TP6 by removing the appropriate plate cover access plugs.
2. Program the UUT to SPCL 909, 548 MHz, 150-kHz FM deviation. Turn EXT AC FM on.
3. Program the HFSSG to 800 kHz, -21.0 dBm.
4. Connect the HFSSG output to TP6 via a BNC to clip lead adapter. Connect the ground clip to the plate cover adjacent to TP6.
5. Connect the WBVM to measure the ac voltage between TP3 and the plate cover adjacent to TP3 (ground).
6. Program the WBVM for dB relative. The reading should be 0 dB.
7. Connect the WBVM to measure the ac voltage between TP4 and the plate cover.
8. Adjust R167 for an indication of  $0.0 \text{ dB} \pm 1 \text{ dB}$ .
9. Replace the access plugs.

**Acquisition Oscillator Level Adjustment, R132****6C-49.****TEST EQUIPMENT:**

- DVM

**REMARKS:**

The acquisition oscillator level adjustment is normally required only when U105 or any associated components are replaced or when the adjustment has been changed or has shifted.

**PROCEDURE:**

Adjust the acquisition oscillator level at TP1 for 2.82V rms with the phase-locked loop disabled.

1. Connect TP5 to TP15 with a clip lead. Connect TP8 to TP15 with a clip lead.
2. Connect the dvm to measure the ac voltage between TP1 and TP15 (ground).
3. Adjust R132 for an indication of  $2.83 \text{ V rms} \pm 0.05 \text{ V}$ .

**A9 SUM LOOP VCO CIRCUIT DESCRIPTION**

**6C-50.**

The A9 Sum Loop VCO PCA produces the fundamental band signal that when further processed in the Output Section, becomes the Signal Generator output. The A12 Sum Loop PCA controls this assembly, which includes four varactor-tuned oscillator circuits that cover the frequency range 480 MHz to 1056 MHz. They are programmed by binary control signals SUMVCO0H and SUMVCO1H as shown in Table 6C-16.

Table 6C-16. Sum Loop VCO Binary Control Signals

BAND	FREQUENCY RANGE (MHz)	SUMVCO0H	SUMVCO1H
1	480 to 624.999999	0	1
2	625 to 759.999999	0	0
3	760 to 894.999999	1	0
4	895 to 1055.99999	1	1

The four oscillator circuits are designed similarly but have different element values and printed transmission line lengths to cover the four bands. Because the four circuits operate the same, the following discussion specifies only the reference designators for the band 1 oscillator. Refer to the A9 Sum Loop VCO PCA schematic in Section 10 to locate corresponding elements for the other three oscillators. (The components for each band are identified on the schematic.)

The band 1 oscillator uses common-base transistor Q4 configured for negative resistance at the emitter. The emitter is coupled to a resonator that consists of a printed transmission line in series with varactor diodes CR7 and CR8 and low loss porcelain capacitors C7 and C8. Two tuning voltage lines connect to the varactor cathodes and anodes via RF chokes L8 and L4, respectively. The cathode lines connect to the vco steering port, J5. The anode lines connect to the vco phase lock port, J6. These ports are used by the A12 Sum Loop PCA to control the operating frequency. The voltage across the varactors, measured between J6 and J5, varies approximately linearly with frequency in each band from about +2V to +20V.

The +13 dBm nominal signal at the oscillator transistor collector is applied to an 8-dB attenuator that provides isolation (R18-R20), and then to a low-pass filter that attenuates harmonics to less than -20 dBc (C51, C52, and printed lines). PIN diode CR12 has low RF resistance and passes the oscillator signal when the oscillator is on, and goes to a high impedance when the oscillator is off.

Band control signals SUMVCO0H and SUMVCO1H are decoded by U5 and Q5 through Q10. This circuit applies bias current only to the selected oscillator transistor. Thus, only one oscillator is activated per band.

PIN diodes CR9 through CR12 connect the active oscillator to a resistive signal splitter consisting of R22, R23, and R50. The first signal splitter output goes to series-connected monolithic 11-dB amplifiers U1 and U2. A -12 dB pad (R26-R28) is located between U1 and U2. Two amplifiers are required for adequate isolation between the Sum Loop and the Premodulator assemblies. The output of U2, at about +7 dBm, is connected to the A32 Premodulator PCA by a plug-in capacitor at J7.

The second signal splitter output goes to an identically configured circuit including amplifiers U3 and U4. Following U4 is a low-pass filter including C69 and C70 that attenuates high frequency harmonics. The filtered output from U4 is connected to the A12 Sum Loop PCA at P1 by a through-the-plate composition resistor. This component behaves as a distributed RC low-pass filter at very high frequencies, and improves sum loop spurious performance.

**SUM LOOP VCO TROUBLESHOOTING**

**6C-51.**

The Sum Loop VCO PCA, along with the A12 Sum Loop PCA, generates the fundamental frequency band. A failure of the Sum Loop VCO can cause Sum Loop Unlock status code 244, or Sum Loop Unlevel status code 245 to appear. A failure of the Sum Loop VCO can trigger self-test error codes 327 through 333. To determine whether the Sum Loop VCO or another assembly has failed, perform the following tests.

1. Ground the phase lock port of the vco with a clip lead (J6, Sum Loop VCO or TP4, Sum Loop).
2. Measure the dc voltage at J5 with the Signal Generator programmed to SPCL 943 (all dac's to full scale). The reading should be +26.00V.
3. Program the UUT to SPCL 942 (all dac's to half scale). The reading should be +13.00V. This tests the vco steering voltage circuit.
4. With J6 still grounded, examine the generator output with a spectrum analyzer while stepping the frequency from 512 to 1056 MHz. The frequency must be within about 2 MHz of programmed frequency.

Bypass the output section by examining the signal at vco output J7 with a 500Ω probe (ground the probe nearby). The level should be about -14 dBm. If the signal is correct, the problem is likely in another PCA. If the signal is incorrect over a frequency band corresponding to one of the vco bands, troubleshoot the associated vco circuit.

The dc voltages can be measured at various circuit nodes with the UUT programmed to frequencies corresponding to the four vco bands. Enable each of the four bands with UUT frequencies of 600 MHz, 700 MHz, 800 MHz, and 900 MHz. Table 6C-17 lists the voltage levels of the Sum Loop PCA.

Table 6C-17. A9 Sum Loop VCO PCA Expected DC Voltages

LOCATION	VOLTS DC
ON bias transistor collector (Q5, Q6, Q7 or Q8, depends on band)	-14.4
OFF bias transistor collectors	0
ON oscillator transistor collector (Q1, Q2, Q3 or Q5, depends on band)	7.8
OFF oscillator transistor collectors	9.4
U1,2,3,4 outputs	4.5
CR9, CR10, CR11, CR12 node	9.7

## SUM LOOP VCO ASSEMBLY ADJUSTMENT

6C-52.

The following procedure covers the R23 amplifier gain adjustment on the A9 Sum Loop VCO PCA.

### NOTE

*This adjustment is not routine and is required only when you replace the associated components, when you change an adjustment, or when either the A12 Sum Loop PCA or the A9 Sum Loop VCO PCA is replaced.*

### TEST EQUIPMENT:

DVM

### REMARKS:

The R23 Amplifier Gain Adjustment should be performed when the following components are replaced:

- A9 Sum Loop VCO: U3, U4, Q1, Q2, Q3, Q4
- A12 Sum Loop PCA: U7, U8, CR4, U1

### PROCEDURE:

Adjust the sum loop modulator voltage to 3.0V dc maximum over the Sum Loop VCO frequency range.

1. Program the UUT to RCL 98, 720 MHz.
2. Connect the DVM to measure the dc voltage between J12 on the A32 Premodulator PCA and ground.
3. Adjust R23 for 3.00V  $\pm$ 0.10V.
4. Step the UUT frequency from 520 MHz to 1050 MHz in 10 MHz steps. Note the frequency where the voltage is greatest. Program the UUT to this frequency.
5. Adjust R23 for 3.00V  $\pm$ 0.10V.
6. Step the UUT frequency from 520 MHz to 1050 MHz in 10 MHz steps. Verify that the voltage is between 1.00V and 3.10V for each frequency.

## Section 6D RF Level/AM

### RF LEVEL FAULT TREE

6D-1.

Refer to the RF Level Fault Tree (Figure 6D-1) when troubleshooting RF Level and AM problems.

### RF LEVEL BLOCK DIAGRAMS

6D-2.

Refer to the RF Level Block Diagram (Figures 6D-2 and 6D-3) to identify the major functional sections and to follow the signal paths of the A31 Output, A33 Mod Control, and A32 Premodulator PCAs.

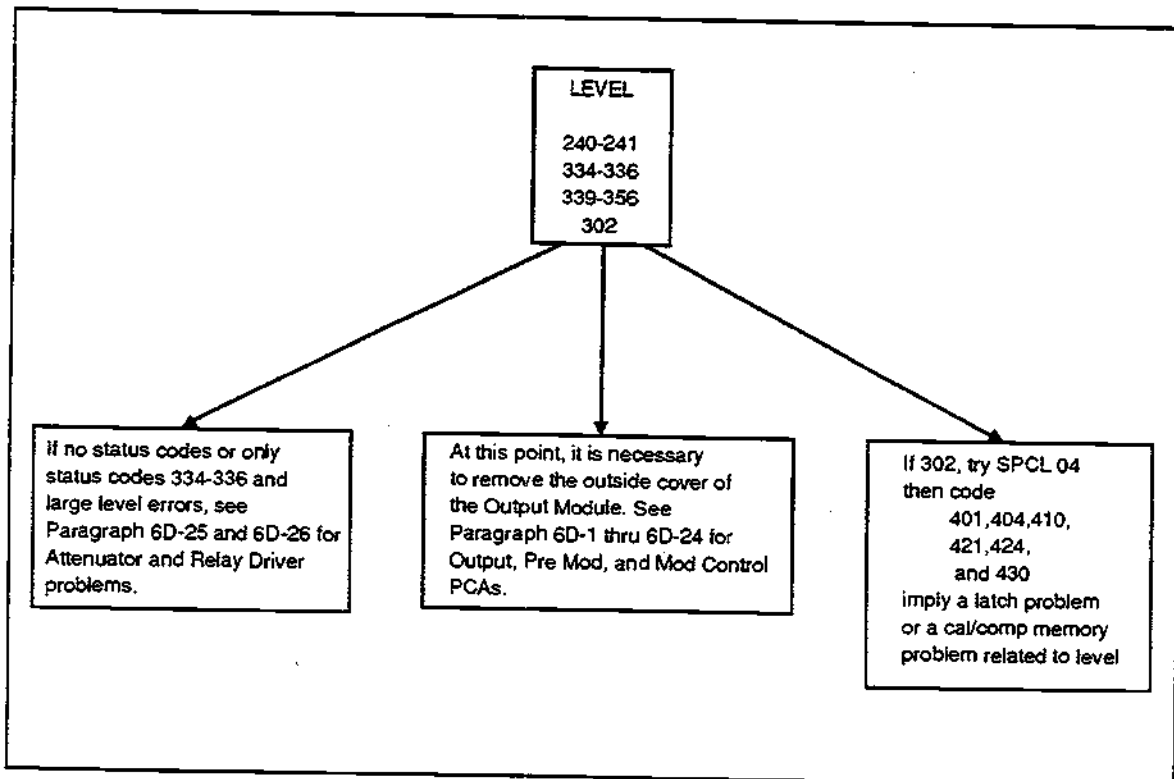

Figure 6D-1. RF Level Fault Tree

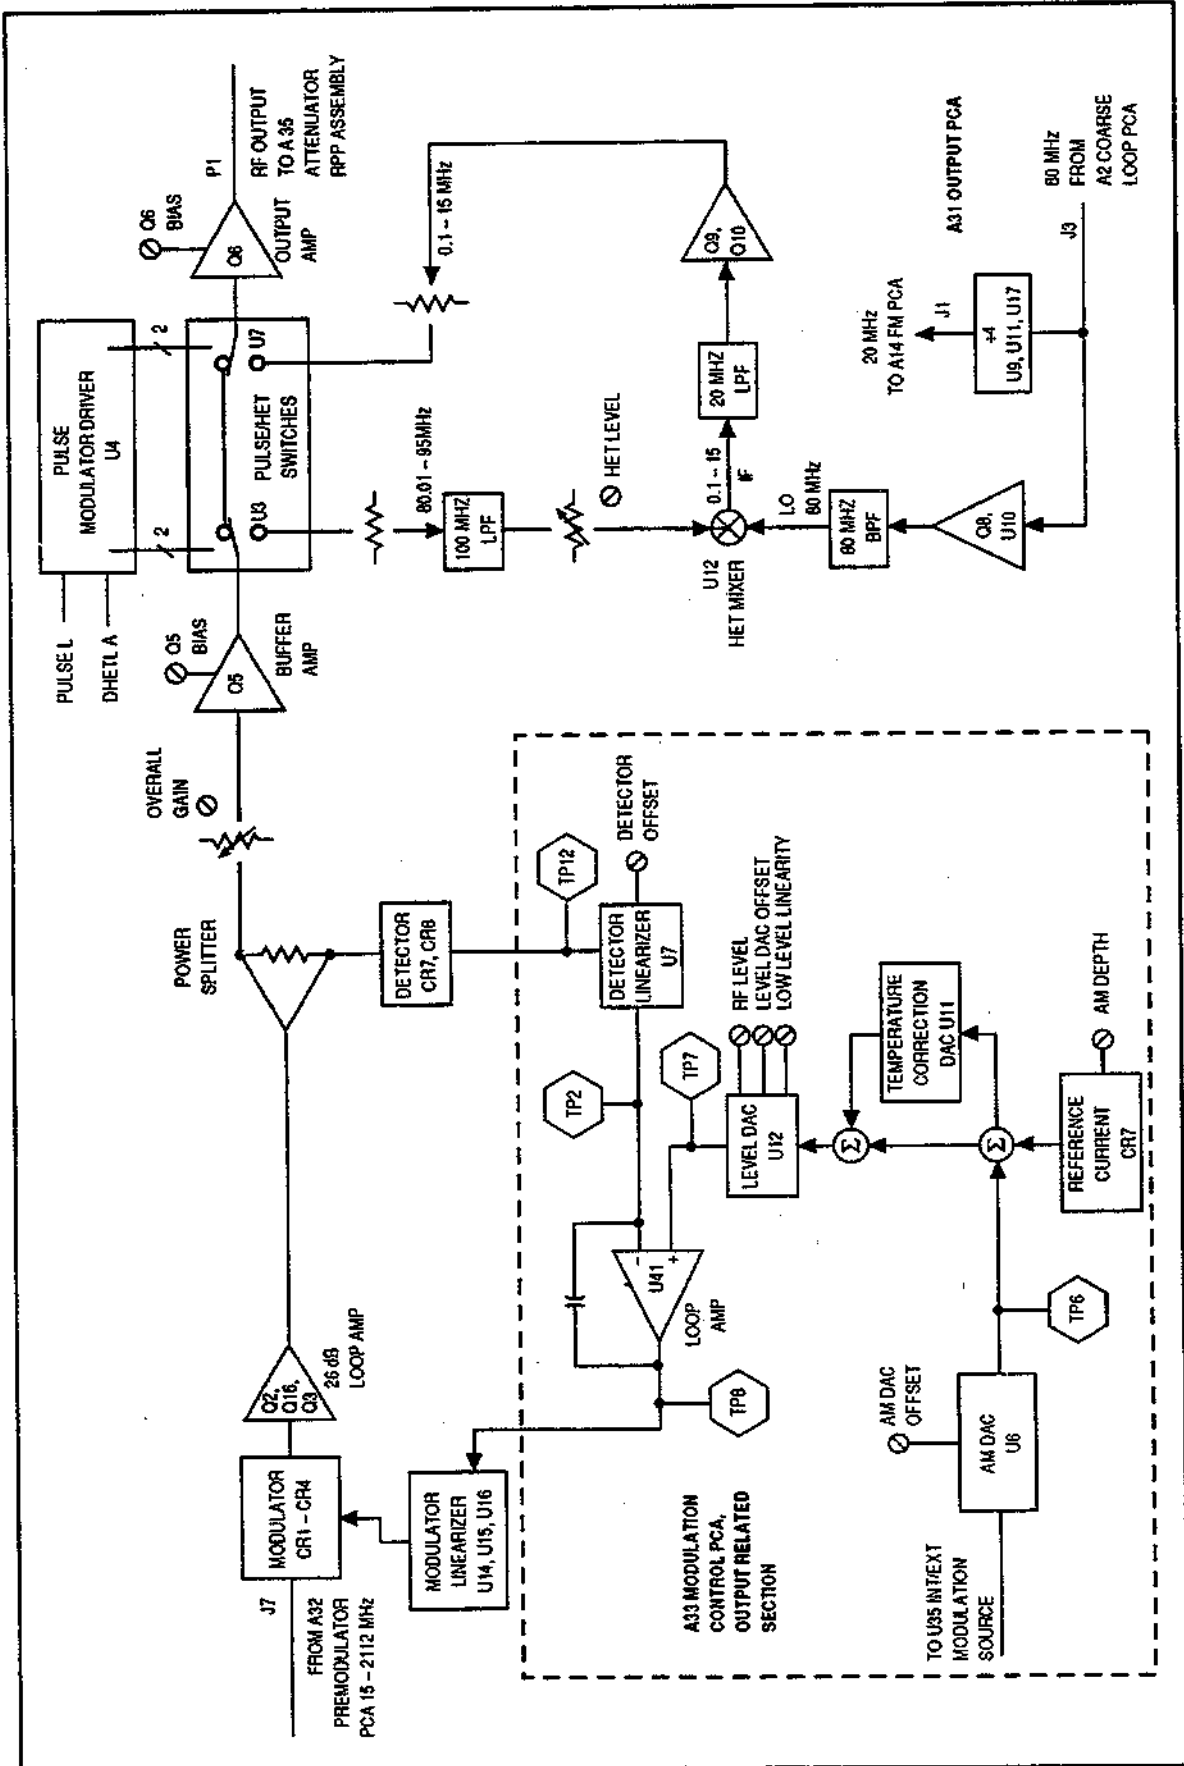

Figure 6D-2. A31 Output and A33 Modulation Control Block Diagram

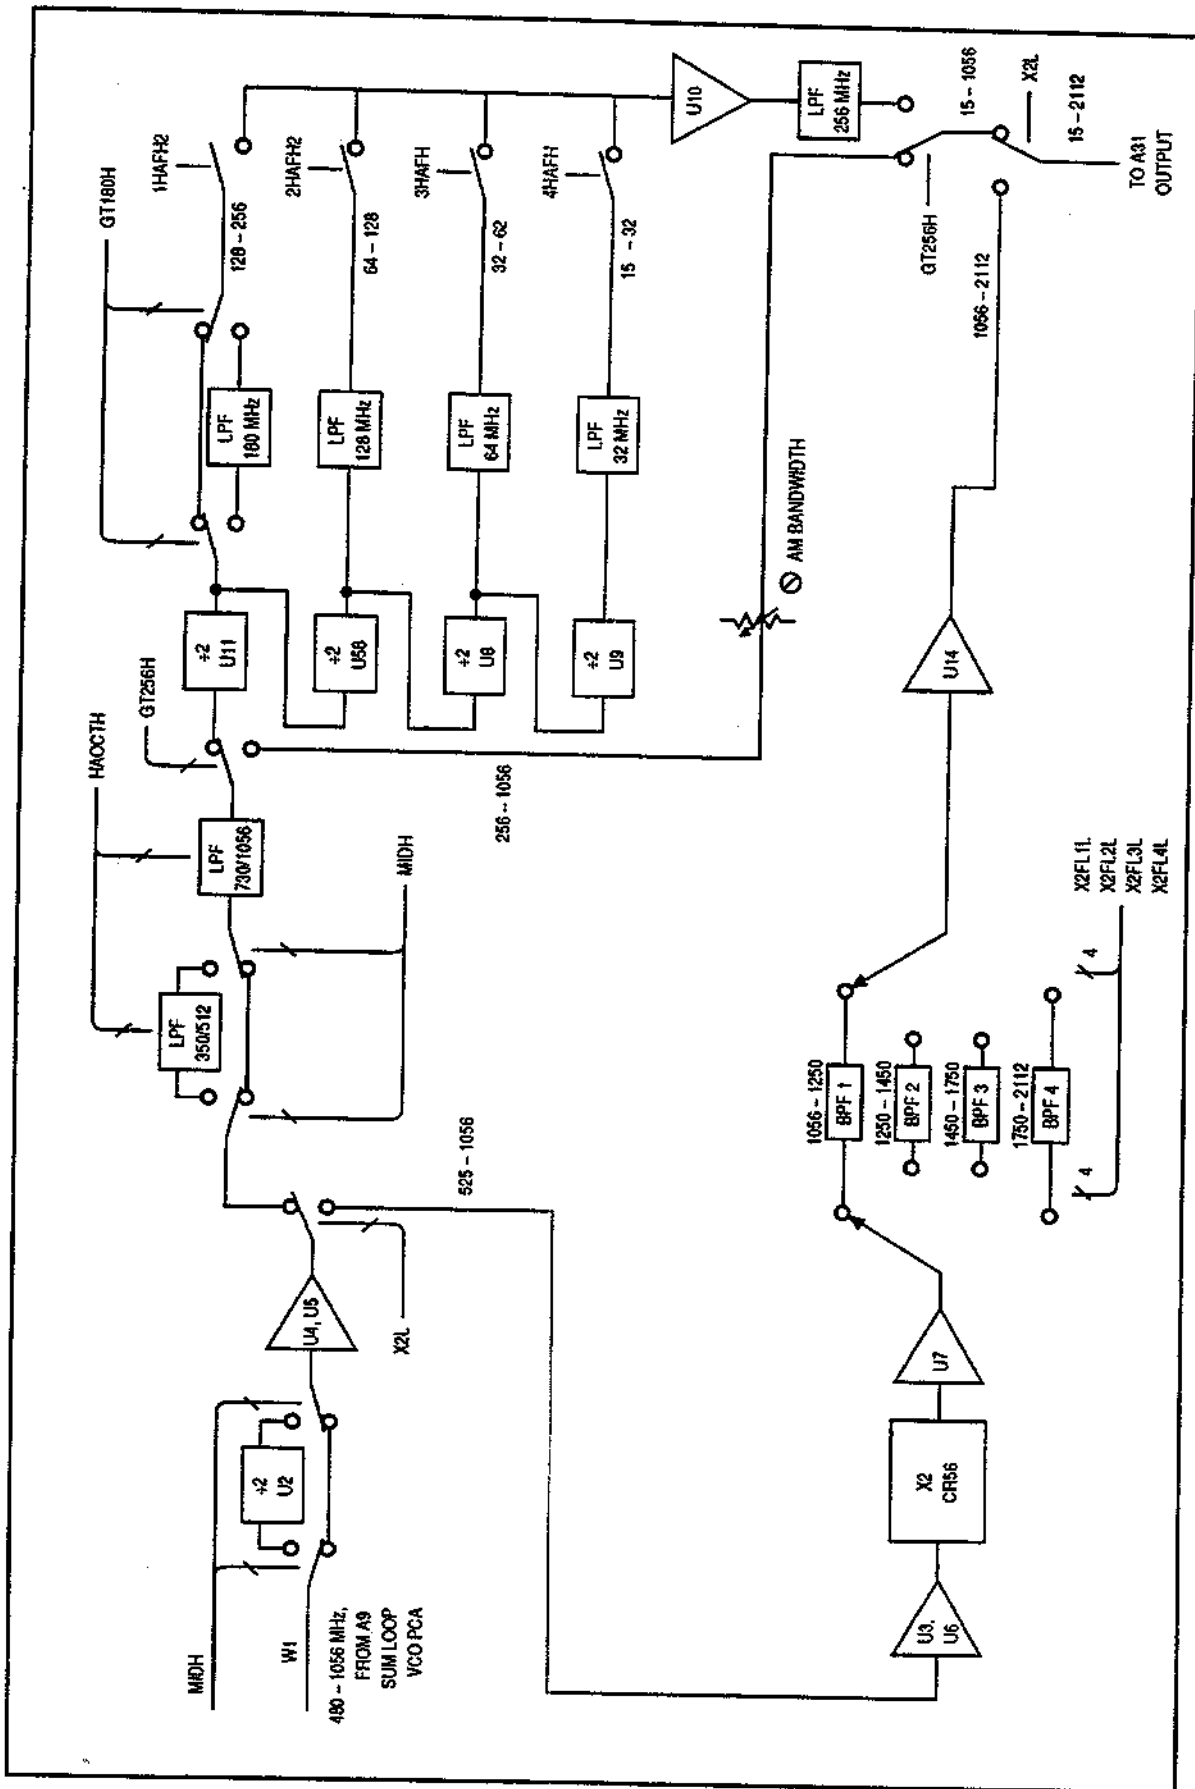

Figure 6D-3. A32 Premodulator PCA Block Diagram

**RF LEVEL CIRCUIT DESCRIPTION****6D-3.**

The Output Assembly consists of the circuits on the A33 Modulation Control PCA, the A32 Premodulator PCA, and the A31 Output PCA. They are interrelated and are described in this subsection as a unit.

The A33 Modulation Control PCA distributes dc power and control signals to the Output PCA, the Premodulator PCA, the FM PCA, and the Sum Loop PCA. It also controls and distributes internal and external modulation signals for AM, FM,  $\phi$ M, and pulse modulation.

The A32 Premodulator PCA receives a 480- to 1056-MHz RF signal from the A9 Sum Loop VCO. The Premodulator PCA uses divide-by-two circuits, switches, and a doubler circuit to develop a 15- to 2112-MHz RF signal. This signal is applied to the Output PCA.

The A31 Output PCA contains the level/am modulator and the pulse modulator circuits. It generates a detected voltage for the leveling loop, develops the 0.1- to 14.999999-MHz het band signal, and provides the final amplification of the 0.1- to 2112- MHz output signal.

The A35 Attenuator/RPP Assembly receives a 0.1- to 2112-MHz RF signal from the Output Assembly. Refer to paragraph 6D-27 Attenuator/Reverse Power Protection (RPP) for details about the A35 assembly. The Attenuator/RPP provides 0 to 138-dB of attenuation in 6-dB steps and provides protection for the output circuits.

**RF Path****6D-4.**

The A9 Sum Loop VCO PCA inputs a 480- to 1056-MHz signal to J5 on the A32 Premodulator PCA. The logic signal (MIDH) controls a circuit that includes CR1 through CR 4, which acts as a double-pole, double-throw (DPDT) switch. The diode circuitry switches the RF signal directly to amplifier U4, or through divide-by-two circuit U2, and then to U4.

Both RF signal paths use frequency-shaping networks to flatten the frequency response. The input frequency to U4 is 240 to 1056 MHz. The signal is then further amplified by U5. The output of U5 is filtered by an 1100- MHz low pass filter, then passes through the X2 band select switch consisting of PIN diodes CR5 through CR8. A switch controlled by logic signal X2L either routes the signal through low pass filter and divider circuits to generate the 15 to 1056 MHz bands, or else to a doubler circuit for 1056 to 2112 MHz.

The 15 to 1056 MHz path begins with a switched filter that is controlled by logic signals HAOCTH and MIDH. This filter removes harmonics with low-pass filters switched at 350 MHz, 512 MHz, and 730 MHz. The particular filter in place depends on the logic state of HAOCTH and MIDH, which control CR9-CR19.

The resulting filtered 240- to 1056-MHz signal goes to the circuitry that includes CR22, CR23, CR31, and CR32, which act as a DPDT switch. The switch circuitry is controlled by logic signal GT256H. This DPDT switch directs the RF signal to an adjustable attenuator including R51, or to the divider chain beginning with U11. The adjustable attenuator serves to equalize level variations in the 256 to 1056 MHz and the 15 to 256 MHz bands.

Divide-by-two U11 has its output split: one branch provides 128- to 256-MHz to a switched filter for reducing harmonics, and a second branch provides an input signal to the third divider, U58. The 128- to 256-MHz output passes through a low-pass filter (selected by logic signal GT180H) for frequencies below 180 MHz. Frequencies between 180 and 256 MHz are filtered by the 260 MHz low-pass filter between U10 and CR31. When a frequency in this band is selected, logic signal 1HAFH2 is high, which turns on CR71. The signal is level-adjusted by the network between CR25, CR27, and CR71.

U58 has two outputs. One output provides 64 to 128 MHz to an output filter consisting of T2 and the low pass filter following it. The second output provides these same frequencies to the fourth divider, U8. U58 is activated when D1HAF1 is high, which provides dc bias, and when D2HAFH is low, which activates the divider.

U8 has two outputs. One output provides 32 to 64 MHz to transformer T4 and the following low pass filter. The second output provides the same frequencies to drive the fifth divider, U9. U8 and its output are selected by logic signals D3HAF and 3HAFH. The fifth divider, U9, generates 15 to 32 MHz. U9 drives transformer T5 and the following low pass filter. U9 and its output are selected by logic signals D4HAF1 and 4HAFH. Diodes CR71, CR28, CR29, or CR30 select the appropriate band, then U10 amplifies it.

The 15 to 1056 MHz signal at the CR31/CR32 junction is applied as one input to a PIN diode band select switch that includes CR47 through CR50, and is controlled by logic signal X2L. The other input is the 1056 to 2112 MHz signal developed by the doubler circuit, described below.

For operation in the X2 band from 1056 to 2112 MHz, PIN diode switch CR7/CR8 directs a 528 to 1056 MHz signal to the frequency doubler and associated amplifiers and filters on the A32 Premodulator PCA. The signal is first amplified and level controlled by U3 and U6, operating in a limiting mode. U6 drives balun transformer T3 at about +14 dBm, which develops a balanced drive for full wave rectifier CR56. The desired second harmonic output from CR56 is attenuated by buffer attenuator R318/R319/R320, and then amplified by U7. Undesired fundamental and third harmonic products are also generated by CR56. The filter bank that follows U7 acts to attenuate these undesired components. U1 is a multilayer stack of four stripline bandpass filters that follows U7. A PIN diode switch routes the signal through one of these filters, depending on operating frequency. The band select logic signals are X2FL1L, X2FL2L, X2FL3L, and X2FL4L, corresponding to frequency ranges of 1056 to 1250 MHz, 1250 to 1450 MHz, 1450 to 1750 MHz, and 1750 to 2112 MHz. For each band, the corresponding logic select signal is low, while the other three are high. The output signal from the switched filters is amplified by U14 and applied to PIN diode CR47, part of the switch that selects between the 1056 to 2112 MHz and the 15 to 1056 MHz bands. The 0 dBm output of this switch, at J16, passes through plug-in jumper capacitor A42C3 to the amplitude modulator on the A31 Output PCA.

The amplitude modulator on the Output PCA consists of PIN diodes CR1 through CR4 and associated components. The modulator receives the 15- to 2112-MHz signal from the Premodulator PCA through plug-in jumper capacitor A42C3 at J7. The modulator is a current-controlled variable attenuator that provides AM and output level control. A balanced topology minimizes even order harmonic generation and avoids post low pass filters. Modulator control currents are determined by a

modulator driver circuit that consists of U14, U15, U16 and associated parts. This circuit provides series diode and shunt diode control currents as a function of a control voltage ranging from 0 to 10V. The voltage to current function was designed so that attenuation is a linear function of control voltage, e.g., modulator output RF signal level at 8V is twice the value at 4V. Linearity is required for constant leveling loop bandwidth. Leveling loop circuits on the A33 Modulation Control PCA provide the modulator control voltage, and are described later.

Q2, Q16, Q3, and associated components follow the modulator in the signal path and form a three-stage, 26-dB gain, 15- to 1056- MHz amplifier. Q2 and Q16 are bipolar parts, while Q3 is a linear power GaAs FET. This amplifier drives a 3-dB power splitter that consists of resistors R38 through R41 and the associated transmission lines. One power-splitter output drives the leveling loop detector diode CR7. The other output goes to an up-tilt attenuator for frequency response compensation, followed by a nominal -7 dB adjustable attenuator that includes CR19 and CR20. This adjustment is required to compensate for gain variations in the three stage 26 dB amplifier. A 7dB gain buffer amplifier, Q5 and associated parts, follows the adjustable attenuator and provides reverse isolation to the detector diode. The buffer amplifier drives U3, a monolithic GaAs SPDT switch. U3 and U7, a similar part, provide the functions of pulse modulation and signal routing for het band operation. U4, U5 and U6 decode logic signals PULSEL and DHETL A and provide control signals to U3 and U7. For 15 to 2112 MHz operation, the signal is routed through U3, C144, C145, and connects to the output amplifier. The output amplifier consists of linear power GaAs FET Q6 and associated biasing components. For pulse operation in this band, U3 and U7 toggle to the other position, providing more than 80 dB isolation. Note that het band circuits are without power in this band, and thus contribute no spurious signals.

For het band operation (0.1 to 15 MHz), the signal from buffer amplifier Q5 is routed through U3 to the het band circuits. This 80.1 to 95 MHz signal passes through a 7 dB pad, then through a 95-MHz lowpass filter that includes C44 through C47. The signal then passes through an adjustable pad (R96), and is applied to the RF input of double balanced mixer U12. The adjustable pad equalizes level in the het and fundamental bands. The 80 MHz local oscillator (LO) signal for the mixer comes from the A2 Coarse Loop PCA through J3 and is amplified by U10. This signal is then amplified by class C amplifier Q8, which is followed by a band-pass filter and 3 dB pad to provide +18 dBm at the mixer LO port.

The mixer 0.1- to 15-MHz output signal passes through a diplexing low-pass filter (C92 through C96, and R102) that suppresses unwanted mixer spurious products while maintaining a 50Ω load at the mixer IF port. A two-stage IF amplifier consisting of Q9, Q10, and associated components amplifies the filtered IF signal by about 20 dB. The signal is then filtered (C55 through C59) to remove residual RF and LO components, and is routed by switch U7 to the output amplifier, Q6. Q7 and Q12 switch off the +5V power supply for the LO and IF amplifiers to prevent spurious signals from being introduced when the instrument operates in the 15- to 2112-MHz bands. Pulse modulation in het band is obtained by toggling switch U7. PIN diode CR15 is biased on for het band, and further isolates the 80.1 to 95 MHz RF signal from the output amplifier.

The 80 MHz signal from the A2 Coarse Loop PCA at J3 also drives a divide-by-four circuit that includes U17, U9, and U11. The 20 MHz output, at J1, connects to the A14 FM PCA and serves as a reference frequency.

## Leveling Loop

6D-5.

The leveling loop controls the 15- to 2112-MHz signal level at detector diode CR7 on the Output PCA; consequently the power splitter output at C31 is also level controlled. The leveled RF signal is proportional to the leveling loop control voltage that appears at TP7 on the A33 Modulation Control PCA.

Schottky detector diode CR7 generates a temperature-dependent dc voltage. This is also a non-linear function of the applied RF voltage, thus temperature compensation and linearization are necessary. The detector diode signal is low-pass filtered by L12 and C33, and is offset by the voltage across temperature-compensating diode CR8. A current source circuit formed by Q1, Q2, and associated components on the Modulation Control PCA provide bias current for CR20 and CR19.

The offset detector diode voltage at U7 pin 3 on the Modulation Control PCA is linearized by amplifier U7 and its associated feedback components. Potentiometer R28 provides an adjustment for best detector linearity at low RF levels. Thus, the voltage at U7 pin 6 (TP2) is proportional to the RF signal level incident on detector diode CR20 (Output PCA).

The voltage is then divided and applied to U41 pin 2, the loop-integrator/summing amplifier. The leveling loop control voltage (plus any AM) is applied to U41 pin 3. U41 generates the modulator control voltage (TP8) that is applied to the modulator driver circuit on the Output PCA. An additional linearizing network including R35, R36, CR5, CR6, and adjustment pot R55, predistorts the control signal at low levels. R55 adjusts for low level linearity. Amplitude modulation is achieved by summing an appropriately scaled modulation signal with the dc leveling loop control voltage.

The leveling loop is closed by means of the amplitude modulator/modulator driver, on the Output PCA. These circuits, described previously in this section, attenuate the RF signal in proportion to the modulator control voltage at TP8 on the Modulation Control PCA, which varies from 0 to 10V.

Comparator U3 and associated components form an unlevelled indicator circuit. The comparator senses the modulator control voltage at TP8. This voltage is normally less than +11V, and the comparator output is high. If the modulator control voltage exceeds +11V, the modulator attenuation is at a minimum, and the leveling loop becomes inoperative (unlevelled). This condition could be due to a fault or some abnormal operation such as overmodulation. In this case, the comparator output (UNLVLL) goes low. The Controller PCA senses this low and causes the front panel STATUS indicator to flash and displays unlevelled status code 241 if interrogated.

## Level Control

6D-6.

The level-control circuit sets the instrument output level. This audio signal processing circuit receives inputs from the internal and external modulation signals, a dc reference voltage, and the digital control commands. The circuit outputs the leveling loop control voltage that provides vernier level control and amplitude modulation control of the signal generator output. The A13 Controller PCA provides digitally encoded level, modulation depth, and temperature-compensation information.

External AM signals are cabled to J13, pin 1 on the Modulation Control PCA. This point is monitored by an ac peak detecting voltmeter composed of comparator U16, U17 and associated components. A similar circuit monitors external FM signals. Both circuits share a common reference circuit, R70 through R74 and CR12. These components provide voltages of 1.02V at U16 pin 8 and 0.98V at U16 pin 10. When these voltages are exceeded, these comparators trip and trigger monostable multi-vibrators U17A and U17B to provide indication to the controller that the peak ac voltage is not 1V.

Analog switch U5 selects the internal or external dc- or ac-coupled modulating signal, or selects no modulation. The selected signal is buffered by U21 and is applied to U6 pin 19, a multiplying 12-bit dac. U6, with amplifier U8-A, acts as a digitally programmed variable attenuator that controls AM depth. Op amp U8-B sums the AM signal (at TP6) with a dc-reference current provided by CR7. The output at U8-B pin 8 is the 1+AM signal. This signal, with additional scaling, is the basis for level and AM depth. AM depth adjustment is provided by potentiometer R10 and AM dac offset is provided by R8.

The instrument RF output amplitude is temperature compensated in a frequency-dependent manner. The 1+AM signal is applied to the reference input of U11, an 8-bit multiplying dac, and to one input of summing op amp U8-D. The dac output, at U8-C pin 1, is the 1+AM signal scaled by a factor that is generated from stored, RF frequency dependent constants. This voltage is applied to an amplifier with temperature-dependent gain that includes U8D, R15, R16, R18, and RT17. This amplifier produces a temperature compensated 1+AM signal at U8-D pin 14.

This 1+AM signal is applied to the reference input of level dac U12. This 14-bit multiplying dac, with op amp U4, generates the leveling loop control voltage (at TP7). The leveling loop control voltage is the temperature compensated 1+AM signal multiplied by a factor proportional to the 14-bit level control number provided by the Controller PCA. The signal generator RF output level adjustment is provided by potentiometer R20, and dac offset voltage adjustment is provided by potentiometer R23.

## RF LEVEL TROUBLESHOOTING

### 6D-7.

If the signal generator level is inaccurate or an unleveled condition exists, the Output assembly (A31, A32, and A33), or the A35 Attenuator/RPP Assembly is probably at fault. If an unleveled condition exists, check the RF circuitry prior to the detector, the detector circuitry, or the dc part of the leveling loop circuitry. Refer to the heading "Unleveled Condition" later in this section.

If there is no unleveled condition, the problem is likely in the circuitry following the detector. This circuitry includes the buffer amp Q5, the heterodyne circuit, the pulse modulator, the output amplifier Q6, and the A35 Attenuator/RPP Assembly. If the level problem exists only below 15 MHz, troubleshoot the heterodyne circuitry. If the level problem exists only in a specific frequency band, check premodulator operation and switched filter operation controlling that band as shown in Table 6D-1. If the problem is not frequency dependent and if the level is accurate above +7 dBm but inaccurate below +7 dBm, check the Attenuator/RPP Assembly.

Table 6D-1. Band, Filter, and Frequency Programming Data

FREQUENCY (MHz)	X 2	X 2 F L 1	X 2 F L 2	X 2 F L 3	X 2 F L 4	G T 1 8 0	G T 2 5 6	1 H A F	2 H A F	3 H A F	4 H A F	M I D	H A O C T	H E T
0.1 to 14.999999	0	0	0	0	0	0	0	0	1	0	0	1	0	1
15 to 31.999999	0	0	0	0	0	0	0	0	0	0	1	1	0	0
32 to 63.999999	0	0	0	0	0	0	0	0	0	1	0	1	0	0
64 to 127.999999	0	0	0	0	0	0	0	0	1	0	0	1	0	0
128 to 179.999999	0	0	0	0	0	0	0	1	0	0	0	1	0	0
180 to 255.999999	0	0	0	0	0	1	0	1	0	0	0	1	0	0
256 to 349.999999	0	0	0	0	0	1	1	1	0	0	0	1	1	0
350 to 511.999999	0	0	0	0	0	1	1	1	0	0	0	1	0	0
512 to 729.999999	0	0	0	0	0	1	1	1	0	0	0	0	0	0
730 to 1055.999999	0	0	0	0	0	1	1	1	0	0	0	0	1	0
1056 to 1249.999999	1	1	0	0	0	1	1	1	0	0	0	0	0	0
1250 to 1449.999999	1	0	1	0	0	1	1	1	0	0	0	0	0	0
1450 to 1749.999999	1	0	0	1	0	1	1	1	0	0	0	0	0	0
1750 to 2112.000000	1	0	0	0	1	1	1	1	0	0	0	0	0	0

If the level problem is not in a particular frequency band, troubleshoot at a low frequency where an oscilloscope is useful. Select SPCL 01 to place the instrument into a known state, set the frequency to 88 MHz, and the amplitude to +13 dBm. Verify the voltage at TP8 on the Modulation Control PCA is  $+1.4 \pm 0.5V$  dc. If this voltage is correct, the problem is localized to the Output PCA circuits following the detector diode CR20 or the Attenuator/RPP assembly. The appropriate signal levels following this point are as follows:

- R42, 1.2V p-p
- Q5 base, 0.5V p-p
- Q5 collector, 1.3V p-p
- CR15 anode, 1.1V p-p
- Q6 gate, 0.8V p-p
- Q6 drain, 4.5V p-p
- P1, 3.5V p-p

These voltages are approximate and are as measured with a 10 M $\Omega$ , 8 pF, oscilloscope probe using a ground connection with less than 1 inch of lead length. Make the ground connection at the probe tip.

### Unleveled Condition

### 6D-8.

If the problem exists in a specific frequency band (or bands) and other bands work properly, check band control signals and band switches. See Table 6D-1 for band control signal state definition and Table 6D-2 to determine PIN diode states on the Premodulator PCA for various frequency bands. A specific band (or bands) problem will most likely involve a divider, a switch, a filter, or a control signal. If all of the

Table 6D-2. Frequency Band Logic States, A32 Premodulator PCA

FREQ BAND MHz	PIN DIODES TURNED ON, A32 PREMODULATOR PCA, CR NUMBERS																							
	1	2			9	11	14	17											35					
	3	4	5	7	10	12	15	18	22	23	24	26							33	36	39	43		
																			37	40	44			
																			38	42	45	47	48	
0.1 to 15-	x		x		x			x	x			x												x
15 to 32-	x		x		x			x	x			x								x				x
32 to 64-	x		x		x			x	x			x									x			x
64 to 128-	x		x		x			x	x			x									x			x
128 to 180-	x		x		x			x	x			x												x
180 to 256-	x		x		x			x	x			x												x
256 to 350-	x		x		x			x				x												x
350 to 512-	x		x		x			x				x												x
512 to 730-		x	x					x				x												x
730 to 1056-		x	x					x				x												x
1056 to 1250-		x			x			x				x								x				x
1250 to 1450-		x			x			x				x								x				x
1450 to 1750-		x			x			x				x									x			x
1750 to 2112-		x			x			x				x										x		x

frequency bands are affected, the leveling loop or associated controls and inputs are probably at fault. First, check the signal at the test connector (J20) of the Premodulator PCA. Note that plug-in capacitor A42C3 must be removed from its normal position and installed in the test position to route the signal to J20. As the instrument frequency is incremented from 15 to 2112 MHz, verify a corresponding signal is present at J20. The levels typically range from -3 dBm to +3 dBm, depending on operating frequency. Level at 690 MHz should be -2.5 dBm ± 1 dB. Also check the input signal to the Premodulator PCA (at J5) from the Sum Loop VCO (A9). These levels should be approximately +7 dBm.

If the Premodulator PCA output appears to be correct, the problem is on the A33 Modulation Control PCA, the A31 Output PCA (between the input, W1, and the detector diode, CR20), or possibly on the A13 Controller PCA.

With the instrument programmed for SPCL 01, frequency set to 88 MHz, and level set to 13 dBm, the voltage at TP7 (leveling loop control voltage) should be approximately +1.5V dc. With the RF output programmed off, the voltage at TP7 should be 0V. If these voltages are not correct, look at the Modulation Control PCA circuitry associated with U21, U6, U8, U9, U11, U12, U4, or check inputs from the controller.

With the instrument programmed as in the preceding paragraph, the voltage at TP8 should be +1.4 ± 0.5V dc. In the unlevelled state, the voltage at TP8 should be greater than +11V dc. If the instrument is working properly, signal levels between the modulator and the detector are typically as noted in Table 6D-3.

A high voltage at TP8 cause the ac voltages to be high unless this part of the circuitry is defective. Investigate any dc voltage discrepancies that may indicate the source of the problem.

Table 6D-3. Modulator to Detector, Nominal Voltages

MEASURED AT	VOLTS DC	VOLTS AC @ 88 MHz
C7, both ends	+1.1V	350 mV p-p
Q2 collector	+5.9V	200 mV p-p
Q16 collector	+10.3V	700 mV p-p
Q3 drain	+6.9V	2.4V p-p
NOTE: Measured with a 10 MΩ, 8 pF oscilloscope probe with short ground lead		

If high ac voltages are measured, the unlevelled problem is most likely with the detector diode, CR20, on the Output PCA, or with U7 or U41 and associated circuitry on the Modulation Control PCA.

### Output Assembly Test Point Signal Information

6D-9.

Table 6D-4 presents the nominal characteristics of the signals at the various test points on the Modulation Control PCA. The table shows the range of the signal and the expected value for the instrument preset state (SPCL 01).

Table 6D-4. A33 Modulation Control PCA Test Points Associated with RF Level/AM

TEST POINT	SIGNAL TYPE	RANGE	TYPICAL FOR SPCL 01	SIGNAL DESCRIPTION
TP1	dc	0.98 +/-5 mV	0.980V	Ext. AM/FM level indicator reference
TP2	dc+audio	+14V to 0V	1.2V	Detector Linearizer output
TP3*	N/A			
TP5	dc+audio	0.1 to 4.5V	0.2V (on)	Pulse Modulator to Output PCA
TP6	dc+audio	0 to +2.3V DC	0V dc	AM input scaled by % AM
		0 to +1.7V AC	0V ac	
TP7	dc+audio	0 to +4.0V dc nominal	0.4V dc	Leveling loop control voltage
TP8	dc+audio	-14 to +14V dc nominal	0.8V dc	Modulator control voltage
* This test point is an input for factory test of ALC loop.				

### RF LEVEL ADJUSTMENTS

6D-10.

The Output Section adjustments listed below are covered in the following paragraphs:

- Modulation Control PCA, A33

- R23, level dac offset adjustment
- R8, AM dac offset adjustment
- R28, detector offset adjustment
- R55, low level linearity adjustment
- R10, AM depth adjustment
- R20, RF level adjustment
- R71, external modulation level indicator adjustment
- R99, sum loop steer gain adjustment

- Premodulator PCA, A32  
R51, AM bandwidth adjustment
- Output PCA, A31  
R96, het level adjustment  
R143, overall gain adjustment  
R46, Q5 bias adjustment  
R73, Q6 bias adjustment

Premodulator adjustments R82, R101, and R102 are related to FM performance and are discussed under the heading "Alignment of FM PCA (A14)" in Section 6E.

Adjustments can be made in any order unless it is noted that the adjustment interacts with another adjustment. Adjustments that have interdependent steps must be performed in sequence. If more than one adjustment is necessary, perform them in the sequence presented.

### Mod Control PCA Level DAC Offset Adjustment, R23

6D-11.

#### TEST EQUIPMENT:

- DVM

#### REMARKS:

The level dac offset adjustment is normally required only when U4 or any associated components are replaced.

#### CAUTION

**This adjustment directly affects the output level and should not be made indiscriminately.**

#### PROCEDURE:

With the RF OUTPUT to OFF, adjust the level dac offset, R23 for  $0 \pm 0.5$  mV at TP7.

1. Access R23 by removing both the bottom instrument cover and the bottom module cover.
2. Program the unit under test (UUT) to SPCL 01, and program the RF OUTPUT to OFF.
3. Connect the DVM to measure the voltage between TP7 and ground on the module plate.
4. Adjust R23 for an indication of  $0 \text{ mV} \pm 0.5 \text{ mV}$ .
5. Program the UUT RF OUTPUT to ON.
6. Reinstall the module plate cover and instrument cover when the adjustments are complete.

**Mod Control PCA AM DAC Offset Adjustment, R8****6D-12.****TEST EQUIPMENT:**

- DVM

**REMARKS:**

The AM dac offset adjustment is normally required only when U8 or any associated components are replaced.

**CAUTION**

**This adjustment directly affects the output level and should not be made indiscriminately.**

**PROCEDURE:**

With AM off, adjust the AM dac offset, R8 for  $0 \pm 0.5$  mV at TP6.

1. Access R8 by removing both the bottom instrument cover and the module plate cover.
2. Program the UUT to SPCL 01.
3. Connect the DVM to measure the voltage between TP6 and ground on the module plate.
4. Adjust R8 for an indication of  $0 \text{ mV} \pm 0.5 \text{ mV}$ .
5. Reinstall the module plate cover and the instrument cover when the adjustments are complete.

**Mod Control PCA Detector Offset Adjustment, R28,  
and Low Level Linearity Adjustment, R55****6D-13.****TEST EQUIPMENT:**

- Power meter
- Power sensor (high level)

**REMARKS:**

Operate the UUT at room temperature for at least one hour with the module plate cover in place before continuing with this adjustment procedure. Perform this adjustment when components in the detector or detector linearizer circuits have been replaced.

The detector offset adjustment sets the detector offset voltage, while the low level linearity adjustment affects the CR5/CR6 pre-distorter. These adjustments interact and both must be adjusted according to the following procedure. RF Level adjustment R20 is also adjusted during this procedure. The adjustments affect the AM depth adjustment, R10. Repeat the procedures under paragraphs 6D-14 and 6D-15, in that order, after this adjustment.

**CAUTION**

**The detector offset and low level linearity adjustments directly affect the output level and should not be made indiscriminately.**

**PROCEDURE:**

While operating in fixed range, first adjust the detector offset adjustment, R28 to provide a 20-dB change in output power for a 20-dB change in the level dac. Then adjust the low level linearity adjustment, R55, to provide a 30-dB change in output power for a 30-dB change in the level dac.

1. Access R28, R55, and R20 by removing the instrument bottom cover.
2. Program the UUT to RCL 98 and +11.4 dBm.
3. Program the UUT to SPCL 51 and SPCL 31. These Special Functions enable amplitude fixed range and relative amplitude.
4. Remove access screws from the bottom module plate cover for the detector offset, low level linearity, and RF level adjustments.
5. Zero the power meter.
6. Connect the power sensor to the UUT RF OUTPUT connector.
7. Adjust RF level adjustment R20 for a power meter reading of 11.4 dBm  $\pm$ 0.1 dB.
8. Program the 436A for dB [ref].
9. Use the EDIT knob to program the UUT to -20 dB. Be certain to use the EDIT knob to change the amplitude for this step or special function 51 will be automatically cleared.
10. Adjust the detector offset adjustment, R28, for a power meter reading of -20 dB [ref]  $\pm$ 0.1 dB.
11. Use the EDIT knob to program the UUT to -30 dB.
12. Adjust the low level linearity adjustment, R55, for a power meter reading of -30 dB [ref]  $\pm$ 0.2dB.
13. Use the EDIT knob to program the UUT to 0 dB.
14. Program the 436A for dBm.
15. Repeat steps 7 through 14 until R28 and R55 need no adjustment to meet the -20 dB and -30 dB setpoints.
16. Use the EDIT knob to program the UUT to 0 dB. Program the 436A for dB [ref].

17. Verify that the power meter reading tracks the indicated UUT relative amplitude, to within  $\pm 0.2$  dB, as the UUT is edited down to -20 dB, in 1 dB steps, with the EDIT knob.
18. Verify that the power meter reading tracks the indicated UUT relative amplitude, to within  $\pm 0.4$  dB, as the UUT is edited from -20 to -30 dB, in 1 dB steps, with the EDIT knob. Program the UUT for SPCL 00.
19. Disconnect the power sensor from the UUT, and replace access screws for the detector offset, low level linearity, and RF level adjustments.

### Mod Control PCA AM Depth Adjustment, R10

6D-14.

#### TEST EQUIPMENT:

- DVM
- Modulation analyzer
- Low-frequency synthesized signal generator (LFSSG)

#### REMARKS:

The UUT must be operated at room temperature for at least one hour with the module plate covers in place before continuing with this adjustment procedure.

#### CAUTION

**The AM depth adjustment directly affects the output level and should not be made indiscriminately.**

The AM depth adjustment is normally required only when components in the AM signal processing circuits have been replaced. After this adjustment is made, perform the RF Level Adjustment, R20 (paragraph 6D-15).

#### PROCEDURE:

Adjust the AM depth adjustment, R10, for 90% AM depth as measured with the modulation analyzer when the UUT is programmed to 90% AM.

1. Remove the AM depth adjustment access screw from the bottom module plate cover.
2. Connect the output of the LFSSG to the UUT MOD IN connector and to the DVM using a BNC Tee.
3. Program the UUT to SPCL 01, 350 MHz, +4 dBm, and EXT AM at 90% depth.
4. Program the LFSSG for 1 kHz and a voltage of 0.7071V rms as measured by the DVM.
5. Connect the UUT RF OUTPUT connector to the modulation analyzer input.
6. Program the modulation analyzer to measure AM + Peak, in a 0.05 to 15 kHz bandwidth.

7. Alternately measure +PEAK and -PEAK, and adjust the AM depth adjustment, R10, until the readings are symmetrical about 90%.
8. Reinstall the AM depth adjustment access screw.

**Mod Control PCA RF Level Adjustment, R20**

**6D-15.**

**TEST EQUIPMENT:**

- Power meter
- Power sensor (high level)

**REMARKS:**

The UUT must be operated at room temperature for at least one hour with the module plate covers in place before continuing with this adjustment procedure.

This adjustment is required if any of the following events occur:

- The Output PCA, the Modulation Control PCA, or the Attenuator/RPP Assembly has been replaced.
- The AM depth adjustment is made.
- The overall gain adjustment is made.
- The level dac or any associated components are replaced.
- The RF level adjustment has been inadvertently changed.

**CAUTION**

**The RF level adjustment directly affects the output level and should not be made indiscriminately.**

**PROCEDURE:**

With the UUT programmed to +10 dBm, adjust the RF level adjustment, R20, for +10 dBm output as measured with the power meter.

1. Program the UUT to SPCL 01, 350 MHz, and +10 dBm.
2. Zero the power meter.
3. Remove the RF level adjustment access screw from the bottom module plate cover.
4. Connect the power sensor to the UUT RF OUTPUT connector.
5. Adjust RF level adjustment, R20, for a reading of exactly +10 dBm on the power meter.
6. Reinstall the RF level adjustment access screw.

**Mod Control PCA External Modulation Level Indicator Adjustment, R71 6D-16.**

## TEST EQUIPMENT:

- DVM

## REMARKS:

This adjustment is normally made if CR12 or R70-R74 are replaced.

## PROCEDURE:

Adjust the potentiometer to provide 0.98V dc at TP1. This adjusts both AM and FM indicators, as the remaining levels are set by fixed resistors.

1. Remove the bottom instrument cover and remove the access screws for TP1 and R71.
2. Connect the DVM to TP1 and ground.
3. Set the UUT to SPCL 01 and observe the DVM.
4. Adjust R71 for 0.980V.
5. Reinstall the access screws and bottom cover.

**Mod Control PCA Sum Steer Gain Adjustment, R99****6D-17.**

## TEST EQUIPMENT:

- DVM

## REMARKS:

The Sum Steer Gain Adjustment is normally required only when U32, U36, or any associated components are replaced.

## PROCEDURE:

The sum steer voltage is adjusted to 10.24V with the Sum Loop VCO steering dac set to full scale.

1. Program the UUT to SPCL 01.
2. Program the UUT to SPCL 942. This special function programs all dacs to full scale.
3. Connect the DVM to measure the voltage between J2 pin 14 and module ground.
4. Adjust R99 for 10.24V  $\pm$ 0.01V.
5. Program the UUT for SPCL 00. This clears all special functions.

**Premodulator PCA Bandwidth Adjustment, R51****6D-18.****TEST EQUIPMENT:**

- Power meter

**REMARKS:**

This adjustment optimizes the AM bandwidth in the 256- to 1056- MHz band. Normally this adjustment is performed when changes are made to the A32 Premodulator PCA.

**PROCEDURE:**

Adjust R51 so that the premodulator output is -2.5 dBm at 690 MHz. Assuming that the shape of the control voltage versus frequency curve is typical, this minimizes the overall variation and thereby minimizes loop gain variation and consequently minimizes bandwidth variation.

1. Remove both the bottom instrument cover and the bottom module plate cover.
2. Program the UUT to SPCL 01, 690 MHz, and +7 dBm. Remove plug-in jumper capacitor A42C3 from its normal position between J16, Premodulator PCA, and J7, Output PCA. Install A42C3 in the test position between J16 and E1, Premodulator PCA. Measure the output power at J20, Premodulator PCA with the power meter.
3. Adjust R51 for -2.5 dBm  $\pm$ 0.1 dBm.
4. Remove the power meter and replace A42C3 in its normal position.
5. Reinstall the bottom module cover and the bottom cover.

**Output PCA Het Level Adjustment, R96****6D-19.****TEST EQUIPMENT:**

- Power meter
- Power sensor (high level)

**REMARKS:**

The UUT must be operated at room temperature for at least one hour with the module plate covers in place before continuing with this adjustment procedure.

This adjustment is normally required only when components in the het band circuits have been replaced.

**CAUTION**

**This adjustment directly affects the output level and should not be made indiscriminately.**

**PROCEDURE:**

With the UUT programmed to +9 dBm, adjust the het level adjustment, R96, for equal output power at 14.9 and 15 MHz.

1. Program the UUT to SPCL 01, 15 MHz, and +9 dBm.
2. Zero the power meter.
3. Remove the het level adjustment access screw from the bottom module plate cover.
4. Connect the Power Sensor to the UUT RF OUTPUT connector. Note the power meter reading.
5. Program the UUT to 14.9 MHz.
6. Adjust the het level adjustment, R96, for a reading equal to that previously noted.
7. Reinstall the het level adjustment access screw.

**Output PCA Overall Gain Adjustment, R143****6D-20.****TEST EQUIPMENT:**

- Power meter
- Power sensor (high level)
- DVM

**REMARKS:**

The UUT must be operated at room temperature for at least one hour before continuing with this adjustment procedure.

This adjustment is normally required only when Q5, U3, U7, Q6, or associated components are replaced. Perform the RF Level Adjustment, 6D-15, after this adjustment. Follow this adjustment with the output compensation procedure. See Section 7.

**CAUTION**

**This adjustment directly affects the output level and should not be made indiscriminately.**

**PROCEDURE:**

Adjust attenuator CR19/CR20 to compensate for post-detector gain variations in the RF path. UUT output level is adjusted to 10.4 dBm at a loop control voltage of 1.34V, at 300 MHz.

1. Access R143, R20, and TP7 by removing both the bottom instrument cover and the bottom module cover.
2. Program the UUT to RCL 98 and 10.4 dBm.

3. Connect the DVM to measure the voltage between TP7 (output PCA) and ground on the module plate.
4. Adjust R20 (output PCA) for a reading of  $1.34V \pm 0.01V$ .
5. Zero the power meter, then connect the power sensor to the UUT RF OUTPUT connector.
6. Adjust the overall gain adjustment, R143, for a power meter reading of  $10.4 \text{ dBm} \pm 0.1 \text{ dBm}$ .
7. Disconnect the power sensor from the UUT.

**Output PCA Q5 Bias Adjustment, R46, and Q6 Bias Adjustment, R73      6D-21.**

**TEST EQUIPMENT:**

- Spectrum analyzer

**REMARKS:**

Adjustments R46 and R73 are both covered in this procedure, since they interact. Perform this adjustment only when Q5, Q6 or associated circuitry is replaced. Adjustment is required only when the UUT does not meet the RF harmonic distortion specification. Follow this adjustment with the overall gain adjustment, R143, then the output compensation procedure in Section 7.

**PROCEDURE:**

RF harmonic distortion is minimized by adjusting R46 and R73 on the Output PCA.

1. Perform the RF harmonic distortion performance test under paragraph 3-12, steps 1 through 7.
2. If the UUT passes this test, R46 and R73 do not require adjustment. If the UUT fails, continue with this procedure.
3. Remove the bottom instrument cover. Remove R46 and R73 access screws from the bottom module plate cover.
4. Connect the UUT RF output to the RF spectrum analyzer input.
5. Program the UUT to +13 dBm and 10 MHz.
6. Set the RF spectrum analyzer to display the UUT output signal and its harmonics (at least three harmonics where possible). Be careful not to overload the analyzer input, since overloading can cause the analyzer itself to generate harmonics, thus invalidating the test.
7. Edit the UUT frequency from 10 MHz to 1450 MHz, in 10 MHz steps. Observe harmonic levels relative to fundamental signal levels. Note the UUT frequency with the highest harmonic levels. Program the UUT to the noted frequency.

8. Adjust R46 to minimize the level of displayed harmonics, relative to the fundamental level. Repeat step 7. If observed harmonics are always more than 30 dB below the fundamental, do not adjust R73, and go to step 10.
9. If harmonics are less than 30 dB below the carrier, adjust R73 to minimize the level of displayed harmonics, relative to the fundamental level. Repeat step 7. Verify that harmonics are more than 30 dB below the fundamental signal.
10. Reinstall the R46 and R73 access screws.

**FM Gain Adjustment, R82, on Mod Control PCA** **6D-22.**

See "Alignment of FM PCA" in Section 6E.

**FM steer Gain, R101 on Mod Control PCA** **6D-23.**

See "Alignment of FM PCA" in Section 6E.

**ATTENUATOR/REVERSE POWER PROTECTION (RPP)** **6D-25.**

The A35 Attenuator/RPP Assembly consists of the A34 Attenuator/RPP PCA, the A7 Relay Driver PCA, and a metal housing. The Attenuator/RPP PCA mounts inside the housing and the Relay Driver attaches on top of the housing. This assembly mounts to the Output Module, opposite the Output PCA. The output signal of the Output PCA (at PI) is input to the Attenuator/RPP PCA (at J1).

The Attenuator section of the Attenuator/RPP PCA provides an attenuation range of 0 to 138 dB in 6-dB steps through the use of seven, independently cascaded, 50Ω attenuation sections (K1 through K7). The seven sections consists of one 6-dB, one 12-dB, and five 24-dB sections. Each section includes a DPDT relay and a pi attenuator pad. When dc power is applied to the relay, one relay position provides a low-loss through path for the RF signal. When no dc power is applied to the relay, the other position inserts the attenuator into the RF signal path. The Controller PCA controls the attenuation sections through the Relay Driver PCA. The compensation memory on the Controller PCA stores the attenuation correction data for each attenuator. The leveling loop control voltage applies the necessary correction.

The reverse power protection section of the Attenuator/RPP PCA protects the attenuator and the output amplifier from excess applied dc voltage or RF power. C8 provides a dc voltage block. With no dc power applied to the relay, K8 is in the protect position. This position protects against long duration excess RF power.

Detector diode CR1 senses excess RF power and trips the latching comparator circuit (U1-A) on the Relay Driver PCA. This change of state of U1-A passes through U1-D, Q8, and Q9 to remove the dc power from K8. This puts K8 into the protect state. Diodes CR2 and CR1 on the Attenuator/RPP PCA form an RF limiter circuit. This provides protection against short duration excess power events or until K8 can change state, which may take up to 4 ms.

When latching comparator U1-A, on the Relay Driver PCA, changes to the tripped state, the positive voltage on U1-A pin 1 is applied to the inverting input of U1-C causing the output of U1-C to go low (approximately 0V dc). This signal (RPTRPL) informs the Controller that the RPP has been tripped, which causes the instrument to go into the RF OFF state and flashes the STATUS light. Diodes CR8 and CR9 provide bias voltage for the limiter diodes to set the limiting threshold. The excess power detection threshold (for CR1 on the Attenuator/ RPP PCA) is set by the resistor network at the input of U1-A.

## ATTENUATOR/RPP TROUBLESHOOTING

6D-26.

Attenuator problems are most often caused by relay contact problems.

Connect the power meter to the UUT RF OUTPUT connector and check the nominal levels at 100 kHz and 2112 MHz per Table 6D-5 to isolate a faulty attenuator section.

Table 6D-5. Attenuator Levels

ATTENUATOR	PROG LEVEL	SPECIAL FUNCTION	OBSERVED LEVEL (NOMINAL)
6 dB	+6 dBm	--	+6 dBm
12 dB	0 dBm	--	0 dBm
24 dB 1	-12 dBm	--	-12 dBm
24 dB 2	-12 dBm	923	-12 dBm
24 dB 3	-12 dBm	924	-12 dBm
24 dB 4	-12 dBm	925	-12 dBm
24 dB 5	-12 dBm	926	-12 dBm

Use Table 6D-6 to verify proper control of the attenuator sections versus the programmed UUT level. Errors could indicate a failure of the Controller PCA or the Relay Driver PCA, especially Q1 through Q7 and associated circuitry.

To isolate a through-path problem on the Attenuator/RPP PCA, first verify the Output PCA signal, see paragraph 6D-8. If there is an apparent through path problem but one of the observed levels from Table 6D-5 is correct, that associated relay may be at fault.

Another way to isolate a bad relay is to remove the Attenuator/RPP assembly from the module leaving the control/power ribbon cable attached. Connect a grounding lead between the Attenuator/RPP housing and the Output Module. Program the UUT to +10 dBm and check continuity with an ohmmeter from J1 through to C7. Be sure that the RPP is not tripped. Tracing through the Attenuator/RPP may locate a defective relay contact.

Check RPP trip operation using the test points provided on the Relay Driver PCA. Connect a power meter to the UUT RF OUTPUT connector and program the UUT to SPCL 01 and then set level to +10 dBm. A momentary short across the terminals of TP1 should trip the RPP causing the observed output power to drop by more than 30 dB. Failure indicates a problem with U1-A, U1-D, Q8, Q9, K8, or associated circuitry.

Table 6D-6. Attenuator Level Control

AMPLITUDE RANGE IN dBm (CW)	ATTENUATOR SECTIONS INSERTED (INDICATED BY X)						
	A6DB	A12DB	A241	A242	A243	A244	A245
+7.0 to +17.0							
+1.0 to +6.9	X						
-5.0 to +0.9		X					
-11.0 to -5.1	X	X					
-17.0 to -11.1			X				
-23.1 to -17.1	X		X				
-29.1 to -23.2		X	X				
-35.1 to -29.2	X	X	X				
-41.1 to -35.2			X	X			
-47.1 to -41.2	X		X	X			
-53.2 to -47.2		X	X	X			
-59.2 to -53.3	X	X	X	X			
-65.2 to -59.3			X	X	X		
-71.2 to -65.3	X		X	X	X		
-77.2 to -71.3		X	X	X	X		
-83.3 to -77.3	X	X	X	X	X		
-89.3 to -83.4			X	X	X		
-95.3 to -89.4	X		X	X	X	X	
-101.3 to -95.4		X	X	X	X	X	
-107.4 to -101.4	X	X	X	X	X	X	
-113.4 to -107.5			X	X	X	X	X
-119.4 to -113.5	X		X	X	X	X	X
-125.4 to -119.5		X	X	X	X	X	X
-147.0 to -125.5	X	X	X	X	X	X	X

The RPP can be reset by pressing the RF ON button. The RPP itself can be reset by a momentary short across TP2 but this will not reset the rest of the UUT to RF ON. Failure to reset the RPP indicates a problem with U1-B, U1-A, or associated circuitry.

Program the UUT to amplitude fixed range (SPCL 51) and edit the level to -10 dBm using the knob. Place a clip lead short across TP3. This will allow the RPP to trip at low RF levels. Use the EDIT knob and adjust the level upwards in 1-dB steps. The RPP should trip prior to reaching +13 dBm. Failure indicates a problem with CR1 on the Attenuator/RPP PCA or with U1-A, U1-D, Q8, Q9, K8, or associated circuitry on the Relay Driver PCA.

## Section 6E

# Frequency and Phase Modulation

### FM/ $\phi$ M FAULT TREE

6E-1.

Refer to the FM/ $\phi$ M Fault Tree, Figure 6E-1, when troubleshooting FM/ $\phi$ M problems.

### FM/ $\phi$ M BLOCK DIAGRAM

6E-2.

Figure 6E-2, the FM/ $\phi$ M Block Diagram, illustrates connections and signal paths between the A6 Mod Oscillator PCA, the A33 Modulation Control PCA, and the A14 FM PCA that are discussed in this section. In addition, the diagram details the major functional sections and signal paths of the FM section.

### FM/ $\phi$ M CIRCUIT DESCRIPTION

6E-3.

The A14 FM PCA controls correct ranging and frequency modes for the Signal Generator's FM and  $\phi$ M function. (See the A14 FM PCA schematic diagram in Section 10.) The FM phase-locked loop consists of the following:

- An 80-MHz voltage-controlled oscillator that operates in one of two selectable bandwidths. The oscillator has a modulation port, a control port, and a presteering section.
- Programmable dividers for reference and variable frequencies.
- Selectable normal and wide range phase detectors.
- Loop amplifier and filter circuitry.
- Logic circuitry.
- Modulation section with both high modulation rate and low modulation rate paths.

The A33 Modulation Control PCA circuitry processes input signals that are used for modulation. The tasks of this PCA include: internal or external signal selection, input amplitude sensing, signal polarity, level venier, and dc FM oscillator steering.

The A6 Mod Oscillator PCA provides the internal FM signal to the Modulation Control PCA.

Refer to Section 2, Theory of Operation for additional discussion about the frequency and phase modulation circuits.

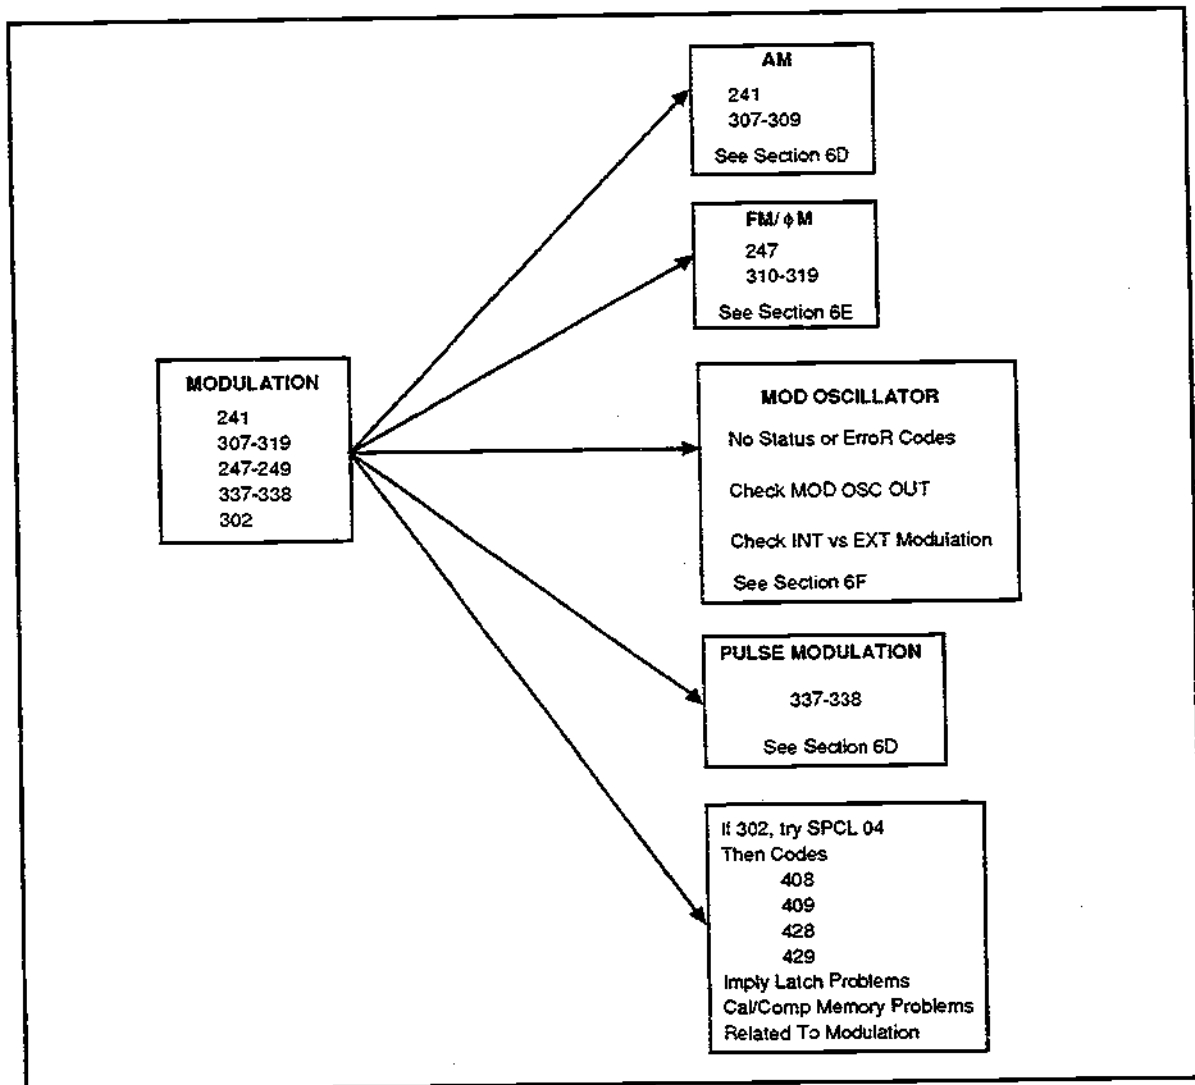

Figure 6E-1. FM/φM Fault Tree

### Oscillator Section

### 6E-4.

The voltage-controlled oscillator (vco) section includes two variable components: L1 and C9, along with varactors (voltage variable capacitors) CR1-CR8, and associated capacitors. Capacitors C2 and C4 couple the resonant circuit to the input of active circuit Q1 and Q2. Capacitors C10, C11, and C13 couple the circuit to the output of the active circuit. Q3 and Q4 provide clean power supply voltages of +14V dc and -14V dc, respectively.

The oscillator operates in one of two modes: the normal high "Q" mode, and the high deviation mode. The normal mode is the default setting. The oscillator can be reconfigured to a high deviation mode, which provides greater bandwidth to attain the wide deviations needed in the two upper bandwidths.

Components C9, CR15, and L4 switch between the high deviation mode and normal mode. Depending on the level of control line HIDEVL, Q5 and Q8 drive PIN diode CR15 between either conduction or high impedance. Conduction (low impedance) adds C9 into the resonant circuit for a normal mode high "Q" oscillator circuit. High

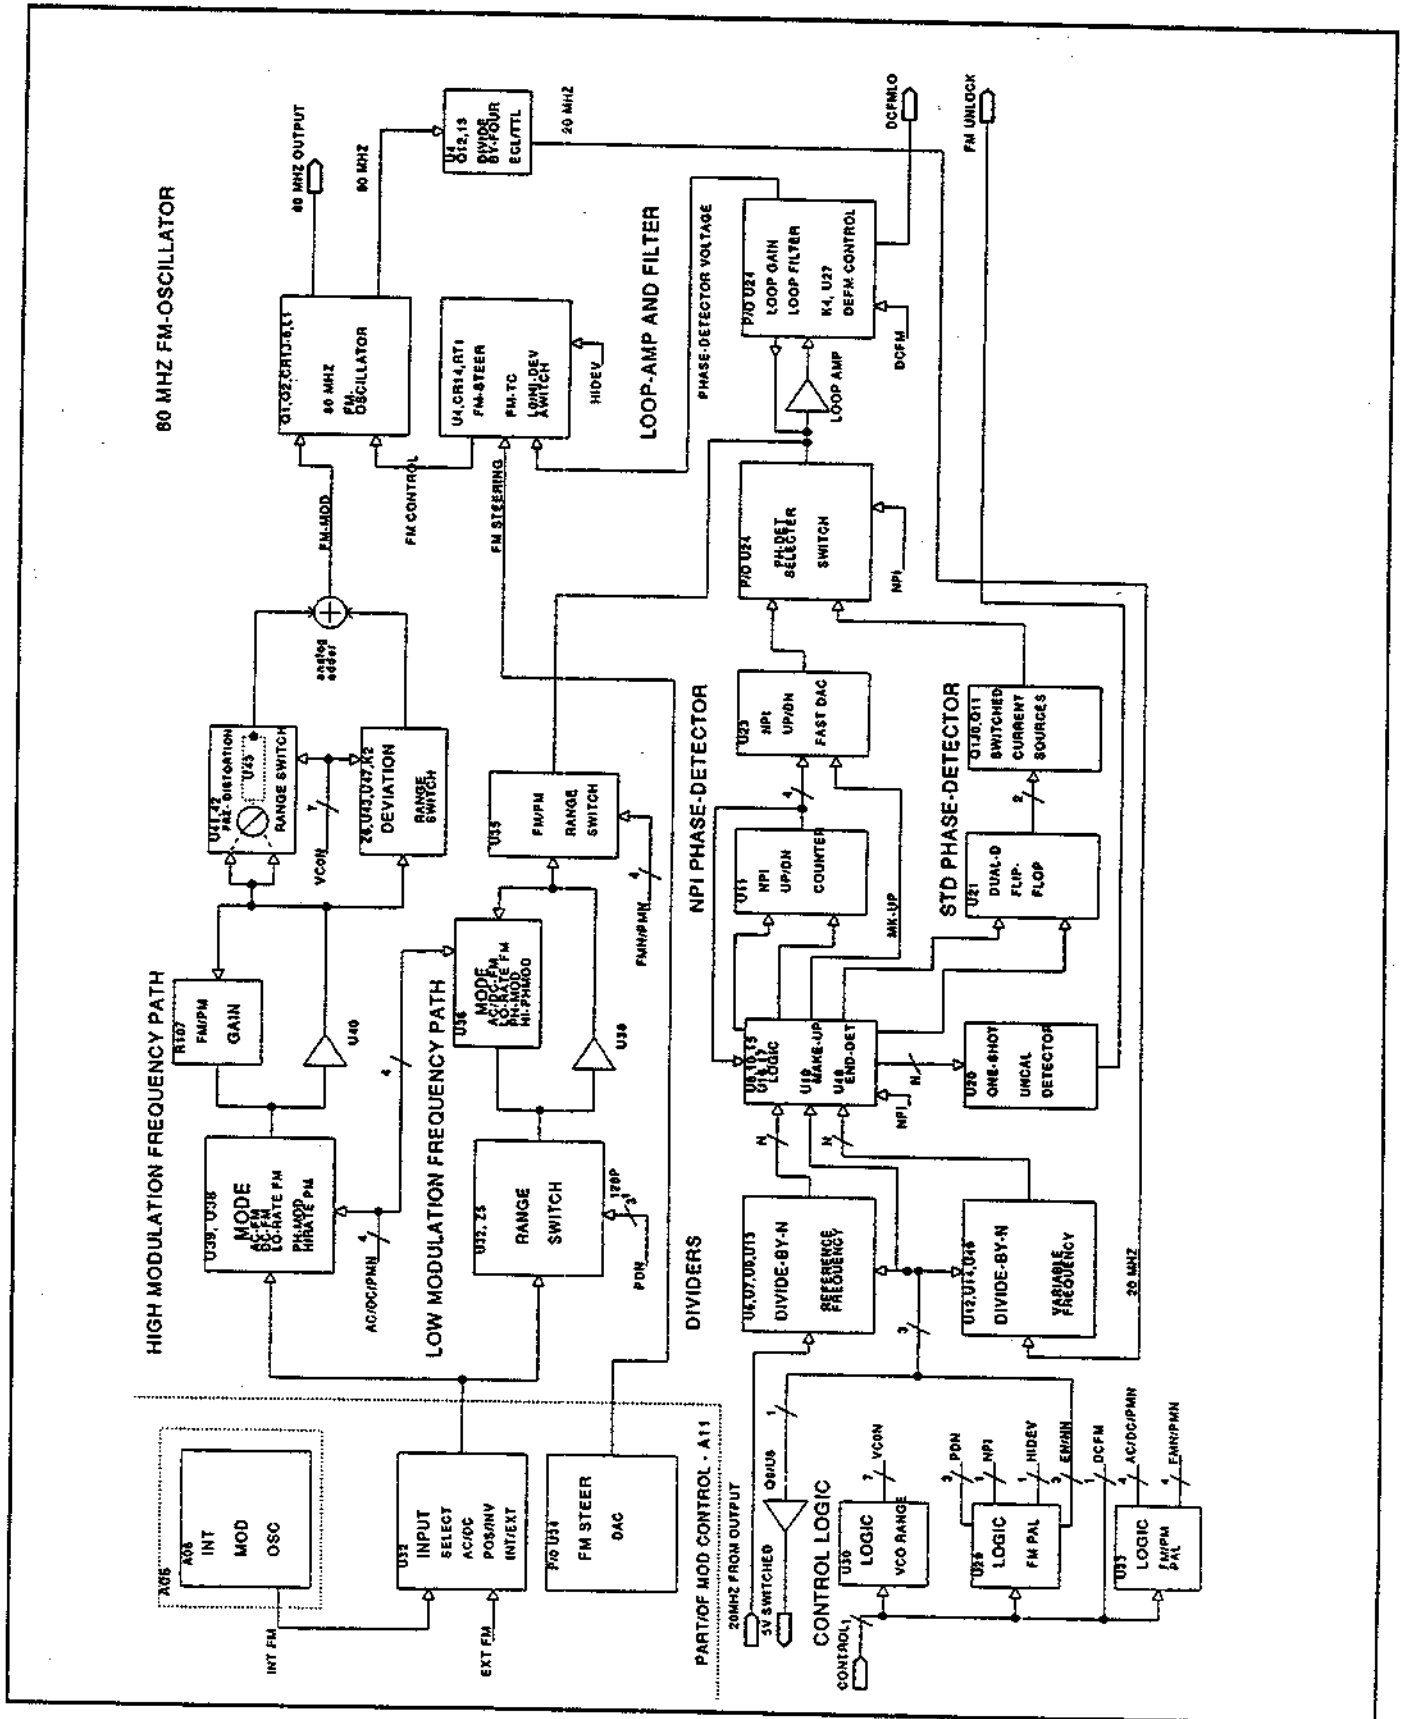

Figure 6E-2. FM/PM Block Diagram

impedance removes C9 from the oscillator during the high deviation mode. Depending on whether C9 is in conduction or high impedance, the varactor voltage adjusts to compensate for the change in capacitance of C9. The varactor voltage both controls and modulates the circuitry.

A control voltage applied to the center connection of the varactors (TP11) keeps the oscillator center frequency at 80 MHz. The cathode voltage is about +15V dc for normal high "Q" mode and about +7V dc for the high deviation mode. The anode of the varactors is nominally 0V dc with the applied modulation. Other components in the vco section isolate and filter the control and modulation lines.

Amplifier U2 buffers the 80-MHz oscillator output to the A12 Sum Loop PCA. Potentiometer R45 and its associated resistors adjust and establish the proper input level. U1 buffers the 80-MHz signal, and U3 and its resistors establish ECL levels to the divide-by-four IC, U4. The 20 MHz signal from U4 is translated from ECL level to TTL level by Q12 and Q13.

During the dc FM mode, a steering circuit made up of quad op amp U5, and Q6 and Q7, keeps the oscillator frequency centered. Diode CR14 provides a stable voltage reference used to control varactor voltages as required. Op amp U5A, Q6, the FM-STEER and V-TC-COMP inputs, potentiometers R35 and R39, and associated resistors provide the nominal voltage at Q7 for the programmed voltage V-PROG at TP2. This voltage is divided by the resistor string of R40, R41, R74, and R133, along with the loop control voltage PH-DET at TP12 and provides the voltage VCO-CONTROL for correct oscillator frequency. The control line HIDEVL is programmed by the instrument control to select HI DEVIATION.

The remaining sections of U5 with RT1, a temperature-sensitive resistor, provide the temperature compensation signal V-TCCOMP (TP9).

### Divider Section

6E-5.

The divider section consists of two programmable divider sections: the reference frequency divider and the variable frequency divider. The reference frequency divider consists of U7, U8, U9, U10, and U13. The variable frequency divider consists of U12, U14, U15, U16, U17, and U49.

Each divider section respectively divides the reference frequency and the variable frequency by the same division. The divider sections receive 20 MHz and divide it to one of the following frequencies: 5 MHz, 200 kHz or 50 kHz, which is a division by 4, 100, or 400 from the 20 MHz, or is 16, 400, or 1600 from the 80 MHz FM oscillator. Both dividers are programmed by the control logic to divide by the same division ratio. The modulation mode (normal ac FM, dc FM,  $\phi$ M, etc.) and the deviation range (refer to Figure 6E-1) determine the correct division. The lower the range, the less division is required. Less division results in greater bandwidth and less circuit noise.

Each divider consists of three parts: two divide-by-four sections, and a divide-by-25 section. Multiplexers U13 and U49 control each divider section for the correct division. A division by 4 (5 MHz) uses just the first divide-by-four. A division by 100 (200 kHz) uses the first divide-by-four and the divide-by-25. A division by 400 (50 kHz) uses all three divider sections.

Each of the divider sections has different outputs. The reference divider section has two outputs, "RSIG" and "Rck". The variable frequency divider has three output signals: "VSIG", "Vck1", and "Vck2". Within the signals of each divider the signal relationship is fixed, as, for example between RSIG and Rck. But the relationship between the RSIG signals and the VSIG signals can vary in timing as shown by the first and second set of pulses. The output signals are used to control the phase detectors. The relationship of these signals is shown in Figure 6E-3. The reference divider also has a circuit, REF ON/OFF SWITCH, part of U6 and Q9, which controls the 20-MHz input that comes from the A31 Output PCA. The circuit enables the 20 MHz from the Output PCA, except when dc FM is active. These signals drive the phase detectors and are discussed in the following paragraphs.

Figure 6E-3. Divider/Phase Detector Timing Diagram

**Phase Detectors, Loop Circuits, and Logic Section.**

**6E-6.**

Two phase detectors provide for selection of the appropriate frequency: the standard phase detector and the N-PI phase detector. Only one of two phase detectors is active at any time. The first phase detector uses U21 as a normal, standard dual D flip-flop. The other is a wide range, N-PI phase detector that uses up-down counter U11. U21 uses diode-switched resistor current sources; U11 uses switched dac U23. Also associated with the phase detectors and dividers is an unlock detector, U20. This detector responds if an overmodulation or unlocked condition exists at the phase detector divider combination.

The two phase detectors operate at the phase detector reference frequency to produce the output signals. The output signals are related to the phase relationship of the fm-oscillator divider combination and to the phase of the reference frequency divider combination.

One of the phase detectors is programmed active. Analog switch U24 selects the output of the active phase detector and amplifies the signal in the integrating loop amplifier U25. The result is filtered in the low-pass filter (L5-7) and its associated capacitors to reduce the modulation of the 80-MHz FM oscillator by the phase detector reference frequency. The filtered output drives the VCO-CONTROL port of the 80-MHz FM oscillator to achieve phase lock and maintain correct center frequency.

## FREQUENCY AND PHASE MODULATION

One of two outputs in the standard phase detector U21 is a pulse whose duty cycle is related to the phase relationship of the inputs. The other output becomes active for wide phase deviation. These output signals drive the voltage level-shift circuits, Q10, Q11, and connected resistors, which drive diode (CR20-24) switched resistor current sources. These current pulses are passed through analog switch U24A to the virtual ground input of loop amplifier U25. The average current, proportional to the phase error between the FM oscillator and the reference, is combined with a fixed current in the input. The difference in current is then amplified in the integrating loop amplifier U25 and phase locked, as discussed in the previous paragraph.

For the wide deviation range N-PI phase detector, the reference and variable frequency dividers alternately clock up/down counter U11 between two states with Rck and Vck signals. Refer to Figure 6E-3. The up/down counter output four bits connect to the four most significant bits of dac U23, alternating the dac between two states of its total range of 16 states. This output is converted to a voltage output in an op amp, U50, and into a current output with resistors R134 and R94 to drive through analog switch U24 into loop amplifier U25. The alternating action of up/down continues smoothly as long as the up/down inputs do not coincide.

To prevent coincidence problems from occurring, an approaching coincidence condition is detected with one part of the OVERLAP PULSE AND COINCIDENCE detector, U19, using the divider outputs "RSIG" and "VSIG". The "RSIG" input connects to the "D" input of a first D flip-flop, and "V" connects to the clock input of the same flip-flop. This sets up the flip-flop and Vck1/Vck2 switch, U18, so that the second flip-flop, U19 will make an overlap pulse, clocked by signal "Vck1" and reset by signal "Vck2" to drive the dac least significant bits. Switch U18 causes the up/down counter to use the second "V" clock ("Vck2" instead of "Vck1") for clocking, causing a missing portion. The overlap pulse, which occurs at the time between the "Vck1" and "Vck2" clock signals, just fills in for the missing portion. The smoothing adjustment R88 makes up for inaccuracies of timing and lower order dac bit substitution.

The up/down counter is prevented from wrapping around from either high to low or low to high by end-count detectors, inverters, and four-input NAND gates that control the appropriate clock inputs. This control information is also used to determine overmodulation or an unlocked loop condition. This information passes to the uncal detector.

The uncal detector U20 receives these inputs and the inputs from the other phase detector. When the phase detectors are close enough to the edge of normal operation, this will trigger the uncal one-shot, U20, which will stretch out the time of abnormal indication. The output, FM UNLCK, is sent to the instrument controller.

Following the phase detectors is the loop amplifier U25, which in combination with the analog switch, selects the appropriate phase detector and gain resistors, R66 and R87, to control the phase-locked bandwidth. The circuit is followed by the loop filter, which has rejection notches at 50 kHz, 90 kHz, and 200 kHz. This filter rejection reduces the pulses from the phase detectors to maintain minimum spurious modulation of the FM oscillator.

Also associated with the loop amplifier and loop filter are comparator U27 and relay K4, which are used in dc FM mode in the FM PCA. The instrument enables dc-coupled FM under internal software control as follows:

1. Set up normal ac fm, except disconnect the input modulation signals.
2. Monitor the comparator output, DCFMLO.
3. Adjust the FM STEER dac on the A33 Modulation Control PCA, using an appropriate algorithm until the comparator senses nearly zero voltage at TP12. Repeat as necessary.
4. When satisfied with the null at TP12, assert the DCFMH control closing relay K4. This effectively puts TP12 at 0V dc ground, disables the dividers and phase lock, and disconnects the phase modulation path. The input modulation signals are reconnected through a dc path.

ICs U29, U30, and U33 generate the control signals for the rest of the circuits for the different ranges of modulation and the different modes of operation in FM,  $\phi$ M, and DC FM. The inputs are the control lines from the instrument controller, and the outputs control the divider, phase detector, oscillator, and modulation circuits. See the Modulation Control Table (Table 6E-1) for the relationship.

## Modulation Section

6E-7.

The modulation section consists of a high rate modulation path and a low rate modulation path. The modulation signal comes from the A33 Modulation Control PCA at J6. The signal frequency at this point can range from dc to 200 kHz. Full-scale amplitude for each range is 4V ac pk for full deviation at the modulation frequency. The type of modulation is determined following this point. The logic control signals for range switching and type of modulation are generated in two PAL ICs, U29 and U33, and selector U30. Refer to the previous discussion under the paragraph heading "Phase Detector, Loop Circuits, and Logic Section" for more information about logic control signals, and see Tables 6E-1 and 6E-2.

The high rate path consists of U37, U39 through U43, U45 through U47, K2, and Z6. Level translators U37, U45, and U46 operate from TTL (CMOS) level to the drive level for the analog FET (or DMOS) switches that require levels for "off" of nominal -12V dc and for "on" of +12V dc. The mode switch for ac FM, dc FM (as well as low-rate FM), phmod (normal), and high-rate phmod is U39. This switch functions as a one-of-four selector on the input of an amplifier, U40. Adjustments R104 and C75 are used to balance the different modes of operation. Feedback resistors R107 and R108 around amplifier U40 determine the gain of this path. The amplifier output drives the range resistor network Z6 and range switches.

The range switches consist of relay switch K2, analog switches U47, and part of U43. These are controlled by level translators U45 and U46. The modulation signal is also amplified by U41, which drives analog multiplier U42 to generate a second harmonic. The second harmonic is added to the fundamental modulation signal for predistorting the signal to the modulation port of the 80-MHz VCO. This predistortion cancels the distortion of the VCO. The analog switches in U43, along with the associated resistors, control and adjust the correct amount of predistortion for each range. The output of the range network and switches and the output of the predistortion network are added in the summing resistors R126 and R127. The relay K1 shorts out the large resistor R127 for the low deviation ranges (high "Q" mode). The 49.9 $\Omega$  resistor R126 improves low-noise performance. The ranges are labeled for FM modulation; however, there are

+ Radians in Phase Modulation  
 \* Ranges and deviation depend on dialed rf frequency. See specifications.  
 \*\* For column R (under Outputs), 1 is R66, 2 is R87.

corresponding phase modulation ranges, e.g., 4 MHz, is 400 (40) radians, etc. The range and predistortion paths are interactive and require interactive adjustment for each range; range match: R139, R140, or R141, distortion match: R115, R117, or R119, respectively.

The high rate modulation signal and some of the range control logic signals are sent to the A12 Sum Loop PCA to maintain correct operation there. Since this causes an interaction between the Sum Loop PCA and the A14 FM PCA, a lead-lag compensation is made with R120 and C99 controlled by analog switch Q15 and translator U45. The lead-lag compensation is controlled by the range bit FMRN2H.

The low rate modulation path consists of Z5, Z7, U32, U35, U36, U38, and associated components. This path operates in all modes of modulation except in the dc FM mode and the cw mode. A range network and switch, Z7 and U32, in conjunction with a range network and switch, Z5 and U35, relative to the reference frequency determines the modulation range. The modulation signal is applied to the range resistor network Z7, selected by analog switch U32, and applied to the virtual ground input of a first section of dual op amp U38.

The selected feedback network determines the gain and function. The output of the first op amp U38 is processed by the range network Z5 and range switch U35. Potentiometers R102 and R145 determine the gain of the low rate path for ac FM and phase modulation, respectively. The selected feedback network consists of capacitors and resistors: C70 and R95 for ac FM, R98 and C71 for phase modulation, and R146, R147, and C76 for high rate phase modulation.

The active feedback network consisting of a second op amp U38 and resistors R99 and R95, switches from ac FM to low rate FM. Analog switch U36 controls the selected feedback network for various modes. The Z5, U35 range selection is selected in conjunction with the Z7, U32 combination and has a 16-to-1 relationship. The Z5, U35 combination is also selected relative to ac FM or phase modulation.

Table 6E-1 shows the relationship between selected modulation ranges and functions for inputs, controls, and outputs. Table 6E-2 shows the relationship between the modulation ranges and the FM dac values.

## MODULATION CONTROL CIRCUIT DESCRIPTION

6E-8.

The following paragraphs describe the FM modulation circuitry on the A33 Mod Control PCA. Refer to the A33 Mod Control PCA schematic diagram in Section 10. The description is broken into three parts:

- FM input voltage processing
- FM STEER and SUM STEER voltage generation
- FM control signals generation

### FM Input Voltage Processing

6E-9.

The circuits listed below select and amplify the external FM input signal and the internal mod oscillator signal from 1V ac pk to 4V ac pk at the top of each FM range (4 MHz, 1 MHz, etc.). They also provide a vernier output within each range as the controller programs the multiplying dac.

- Op Amp U27
- Associated input resistors, capacitors, and CMOS switches, U39
- DAC U34 and Op Amp U9A
- Inverter/amp U9B

# FREQUENCY AND PHASE MODULATION

0	CW MODE						

Selecting combinations of EXT AC FM or EXT DC FM and INT FM inputs (front panel controls) is done by using the CMOS switches in U39 (and its associated resistors and capacitors) at the input of op amp U27. Potentiometer R82 sets the gain to amplify a 1V ac pk signal to 4V ac pk. The FM DEV dac, U34-1,2 is set to 3600 counts (out of 4096 at full scale).

U34 and op amp U9A produce 4V ac pk to the inverter/ amplifier circuit U9B, which in conjunction with CMOS switch Q6 either amplifies directly or inverts the signal to produce the proper polarity output. This accommodates the instrument action of either over or under programming at the sum loop. The multiplying FM DEV dac U34 is under controller operation to produce a vernier output within each range, or overrange in fixed range, or variation of nominal reference of 3600 counts (out of 4096) for closed-case calibration.

Comparators U16C and U16D, and associated resistors, trigger one-shots U26A and U26B when the peak amplitude of the applied external level is centered around 1V ac pk. The controller responds to deviations from 1V ac pk by alerting the operator by way of front panel "HI" or "LO" indicators.

**FM STEER Voltage Generation**

**6E-10.**

The FM STEER signal is produced by dac, U32 pins 23 and 24, and op amp U36B. The signal ranges between 0 and 10.2V dc (nominally 5.1V dc) and is adjusted with potentiometer R101. The voltage level is regulated by the controller to zero the frequency offset in dc FM.

**FM Control Signals Generation**

**6E-11.**

The controller sends the control signals to the A14 FM OSC PCA where they are latched by U35. These signals are:

- Three range switches: FMRN2H, FMRN1H, and FMRN0H
- Four controls: DCFMH, LOWFMH, PMODH, and HRP MH

**FM TROUBLESHOOTING (A14)**

**6E-12.**

FM troubleshooting is divided into three parts:

- Frequency check
- Modulation check
- Input signals and control input checks

**Frequency Check**

**6E-13.**

Use Table 6E-3 when checking the performance of the FM oscillator for faults in frequency lock. Note the relationship between the modulation frequency and the divider frequencies.

**Table 6E-3. FM Oscillator Frequency Check Table (Normal Operation)**

NOTE: Set SPCL to 909, Frequency to 800 MHz. Have EXT FM input equal zero.										
FM DEV EXT FM	FREQ MHz	VOLTS DC						DIVIDER FREQUENCIES		DETECTOR TYPE
		TP11	TP12	TP4	TP2	TP3	TP9	TP 5,15,6,8 U21		
Off	80	15	0	0	22	6.3	0-1	--*	5 MHz	std U21
50 kHz	80	15	0	0	22	6.3	0-1	200 kHz	200 kHz	std U21
100 kHz	80	15	0	0	22	6.3	0-1	50 kHz	--	NPI U11,23
400 kHz	80	7	0	0	11	6.3	0-1	50 kHz	--	NPI U11,23

\* TP 5, 15 positive pulses; TP 6, 8 negative narrow pulses Tolerances TP 2, 11, 12 = 0.5V; TP 4 = 0.01V; TP 3 0.2V

1. If the frequency is wrong, check the adjustment of oscillator frequency, L1, and C9.
2. If the voltages are wrong at TP11 and TP2, check steering circuit U5.
3. If the divider frequencies are wrong, check the dividers and input drive levels.
4. If the phase detector output at TP12 is high or low, check the phase detectors U11 or U21, current sources U23 and U50, or the Q10 and Q11 circuits.

## FREQUENCY AND PHASE MODULATION

5. Check the low rate modulation path. Op amp U38 should have 0V at the junction of pin 1 and C70.
6. Check CMOS switches U32, U35, U36, U39, U43, and U47 for proper control voltages.
7. Check associated CMOS switch drivers. Use the Modulation Control Table (Table 6E-1) for logic information. For U36, U39, U43, and U47:
  - V-on > +10V dc, nominally +13V dc.
  - V-of < -12V dc.
8. Check for CMOS switch leakage of control voltage to the signal path.

### Modulation Check

6E-14.

For errors and faults in modulation, use Table 6E-4.

Table 6E-4. FM Oscillator Modulation Control (Normal Operation)

NOTE: Set SPCL 909, RF Freq 800 MHz, INTFM DEV 250 kHz @ 1 kHz (Alternate: Use EXTFM with low frequency signal generator, JF 6011 set to 1 kHz and 383 mV RMS into EXT FM input.)			
MOD FREQ	VOLTAGE AT TP4	SIGNAL AT JUNCTION U38-1/C70	SIGNAL TP1
100 Hz	500 mV pk	250 mV pk	4V p-p
1 kHz	500 mV pk	25 mV pk	4V p-p
5 kHz	500 mV pk	< 5 mV pk	4V p-p

To check modulation, proceed as follows:

1. First check the FM input to FM PCA at J6 for 4V pk. If no input is present, check the Modulation Control PCA FM circuitry and inputs.
2. For error at TP4 and TP1, check the high modulation frequency path, U40, etc.
3. For error at the junction of U38 pin 1 and C70, check the low frequency modulation path U38, etc.
4. Check all ranges for correct modulation at the output. Use the Modulation Control Table (Table 6E-1) for the logic levels and the ranges for all FM DEV ranges. Check CMOS analog switches and drivers for proper operation.
5. Check phase modulation for a correct output. If the output is not correct, check the  $\phi$ M circuits associated with U40 for problems at high modulation frequencies. For errors at low modulation frequencies, check the  $\phi$ M circuits associated with U38.
6. For errors in Special Functions LORATE FM and HIRATE  $\phi$ M check the circuits associated with U40 and U38.

7. For errors in dc FM, check circuits associated with FM STEER and U5, circuits with the loop amp U25 and relay K4, and the LODCFM detector U27. Also check the FM steer circuits on the Modulation Control PCA. The process is implemented by the controller.

**Input Signals and Control Input Signals Checks**

**6E-15.**

Check the input signals and control input signals as follows:

1. If the modulation signal is not present at FM PCA J6, check the A33 Modulation Control PCA for the FM dac and amplifiers and switch inverter.
2. If the 20 MHz is not present from the A31 Output PCA, check the switched +5V square wave on J4, and the +5V dc on J7 to the Output PCA.
3. If the control signals are not correct on J1 according to the Modulation Control Table (Table 6E-1), check the latches on the A33 Modulation Control PCA.

**FM ADJUSTMENTS**

**6E-16.**

FM adjustments are made on the following pca's:

- A33 Mod Control PCA (FM modulation section)
- A14 FM Board PCA

Make FM adjustments using the following equipment:

- DMM (Fluke 8840A)
- Modulation meter (HP 8901A)
- LFSSG (Fluke 6011A)
- Spectrum analyzer (HP 8586)
- Oscilloscope (Tektronix)

**Adjustments on the Modulation Control PCA (A33)**

**6E-17.**

*NOTE*

*Perform the following procedure to adjust the modulation circuitry. Other adjustments are covered in other procedures.*

The following procedure describes how to make adjustments to the Modulation Control PCA.

1. Make the following equipment settings:
  - a. Set the UUT to SPCL 909, 800 MHz, 0 dBm, 4 MHz dev, EXT AC FM.
  - b. Set the 8840A DMM to ac volts, autorange.
  - c. Set the 6011A Signal Generator to 1 kHz, 383 mV rms.
2. Connect the 6011A to the UUT EXT FM input and to the 8840A.

## FREQUENCY AND PHASE MODULATION

3. Set the 6011A (as measured by the 8840A) to 707 mV rms. Set the 8840A to ac volts, and autorange. Connect the 8840A to J16-P1 on 4048 Modulation Control PCA. Adjust R82 for 2.828V rms  $\pm 2$  mV.
4. Set the UUT to 700 MHz. Set the 8840A to ac volts, autorange. Connect the 8840A to J16-P1 on the A33 Mod Control PCA. Adjust R102 for a reading of 2.828V rms  $\pm 2$  mV on the 8840A.
5. Set the UUT EXT AC FM off, and set the UUT INT FM on. The 8840A should read 2.828V rms  $\pm 2$  mV rms.

Set the UUT INT FM off, and set the UUT EXT AC FM on.

6. Set the UUT to SPCL 943. Connect the 8840A to J2-P14. Set the 8840A to dc volts. Adjust R99 for 10.24V dc  $\pm 10$  mV.

Connect the 8840A to J1-P3. Set the 8840A to dc volts. Adjust R101 for 10.24V dc  $\pm 10$  mV.

Connect 8840A to J6-P24. Verify that the 8840A reads 10V dc  $\pm 1$ V dc.

7. Set the UUT to SPCL 909. Connect a 50 $\Omega$  termination to UUT EXT PULSE MOD. Connect the 8840A to J4-P5. The 8840A should read 0V dc  $\pm 0.2$ V dc. Press the External Pulse Modulation button on the UUT front panel to on. The 8840A should read 4.2V dc  $\pm 0.2$ V dc.
8. Set the UUT to SPCL 909. Set the 8840A to dc volts, 2V range. Connect the 8840A to TP1 on the 4048 board. Adjust the modulation level sense R71 for 0.98V  $\pm 0.5$ V. Remove the 8840A from TP1.
9. Set the UUT to EXT FM. Set the 6011A to 1 kHz and 383 mV. Connect the 6011A and the 8840A to the UUT FM EXT input.
  - a. Edit the 6011A level until the 8840A reads 0.707V rms. Verify on the UUT front panel that the EXT FM LO and the FM HI annunciators are off.
  - b. Increase the 6011A output voltage to 0.728V rms as measured on the 8840A. Verify that the EXT FM HI annunciator is on.
  - c. Decrease the 6011A output voltage to 0.685V rms as measured on the 8840A. Verify that the EXT FM LO annunciator is on.
10. Set the UUT to SPCL 909, EXT AM. Set the 6011A to 1 kHz and 383 mV. Connect the 6011A and the 8840A to the UUT AM EXT input.
  - a. Edit the 6011A level until the 8840A reads 0.707V rms. Verify on the UUT front panel that the EXT AM LO and the AM HI annunciators are off.
  - b. Increase the 6011A output voltage to 0.728V rms as measured on the 8840A. Verify that the EXT AM HI annunciator is on.
  - c. Decrease the 6011A output voltage to 0.685V rms as measured on the 8840A. Verify that the EXT AM LO annunciator is on.

**Alignment of FM PCA (A14)****6E-18.**

Align the FM PCA as described in the following procedure:

1. Center all pots on the FM PCA. Turn the UUT off. Set the 6011A to 50 kHz at 0 dBm. Connect the 6011A to TP12. Connect the spectrum analyzer to TP11. Adjust L6 for a minimum 50-kHz level. Remove the 6011A and the analyzer.
2. Set the UUT to SPCL 909, 800 MHz, 62.5-kHz dev, 1-kHz mod rate, INT AC FM. Set the 8840A to ac volts, autorange. Connect the 8840A to TP1 on the FM PCA. Adjust R107 for 2.828V rms  $\pm 2$  mV rms. Turn INT AC FM off.
3. Remove the cap from J3 to J17 that connects the FM PCA to the A12 Sum Loop PCA. Connect the counter to J3. Adjust L1 to be flush with the top of its housing. Adjust C9 for a locked 80 MHz as read on the counter.
4. Remove the counter from J3 and connect 436A to J3. Adjust R45 for -5 dBm  $\pm 0.1$  dB. Disconnect 436A from J3. Install the 1000-pF cap from J3 to J17 on the Sum Loop PCA.
5. Connect the 8840A to TP9. Set the 8840A to dc volts. Adjust R44 for 0V dc  $\pm 10$  mV dc.
6. Cover the FM oscillator (Q1, Q2 section only) with a metal cover.
7. Set the 8901A to Auto, FM, +peak, 300-Hz HP, 15-kHz LP. Connect the 8901A to J3. Set the UUT to SPCL 909, 800 MHz, INT AC FM, 1-kHz mod rate, 400-kHz FM dev. Set 8840A to dc volts, autorange. Connect the 8840A to TP11. Adjust L1 for 400-kHz FM dev  $\pm 2$  kHz. The 8840A should read 7V dc  $\pm 100$  mV dc. Set the UUT to 40 kHz FM dev. Adjust C9 for 40 kHz  $\pm 0.2$  kHz dev. The 8840A should read 15V dc  $\pm 200$  mV dc. Repeat these steps until both specs are met. Remove the 8840A from TP11.
8. Set the 8840A to dc volts, autorange. Connect the 8840A to TP12. Set the UUT to 300-kHz dev, INT AC FM on, 1-kHz mod rate. Key SPCL 942 to set FM steer dac to 2048. Adjust R39 for 0.0V dc  $\pm 20$  mV dc.
9. Set the UUT to 200-kHz dev AC FM, INT AC FM on, 1-kHz mod rate. Set the FM steer dac to 2048. Set the 8840A to dc volts, autorange. Connect the 8840A to TP12. Adjust R35 for 0.0V dc  $\pm 20$  mV dc.
10. Set the UUT to INT AC FM, 10-kHz mod rate. Connect oscilloscope channel 1 to TP8 and channel 2 to TP6. Set the UUT for 200-kHz AC FM. Adjust R63 until one pulse on channel 1 is exactly in the middle of two pulses on channel 2. This represents a 50% alignment of the pulses on TP6 and TP8. Set the UUT to 10-kHz dev AC FM. Check for a pulse alignment of 22/78%  $\pm 3\%$ . Remove the scope probes.
11. Set the UUT to INT AC FM, 5-rad  $\phi$ M dev, 5-kHz mod rate. Set the 8901A to FM, AVE, 300-Hz HP, 15-kHz LP, %. Note the 8901A reads 100%. Press the kHz button on the UUT. Adjust R104 for a reading of 102% to 102.2% on the 8901A.

## FREQUENCY AND PHASE MODULATION

12. Set the UUT to 800 MHz, 50-kHz dev, 5-kHz mod rate, INT AC FM. Set the 8901A for +peak, % off, >20-kHz filter, and all other filters off. Adjust R107 for equal plus and minus readings around 50 kHz. Plus and minus readings must be within 0.5 kHz of each other. This is a distortion check.
13. Set the UUT to SPCL 909, 800 MHz, 50-kHz dev, 70-Hz mod rate, int ac FM. Set the 8901A to +peak, >20 kHz filter. Adjust R102 for a 50-kHz reading on the 8901A.
14. Set the UUT to SPCL 909, 800 MHz, 100-kHz dev, 70-Hz mod rate, int ac FM. Set 8901A to +peak, >20-kHz filter, all other filters off. Adjust R94 for a 100-kHz reading on the 8901A.
15. Set the UUT to 50-kHz dev, 5-kHz mod freq, INT AC FM. Set the 8901A to %. The 8901A should read 100%. Check the mod rates in Table 6E-5 to determine if the UUT is within specification.

Table 6E-5. FM Modulation Rate Specifications

MOD RATE (Hz)	SPECIFICATION (kHz)
1000	100 +2% -2%
500	100 +2% -2%
200	100 +2% -2%
100	100 +2% -2%
50	100 +1.5% -1.5%

16. Set the UUT to SPCL 909, 800 MHz, 150-kHz DEV, 25-Hz mod rate, int ac FM. Connect the oscilloscope to the 8901A MOD OUT. Adjust the scope for almost full scale display with one cycle. Adjust R88 for a smooth waveform.
17. Set the UUT to 800 MHz, 5-kHz mod rate, 200-kHz DEV, INT AC FM. Set the 8901A to FM, +peak, 300 Hz HP, 15 kHz LP. Adjust R141 for a 8901A reading of 200 kHz  $\pm$ 1 kHz. Adjust R119 for symmetrical plus and minus readings about 200 kHz  $\pm$ 1 kHz. Repeat until both specs are met.
18. Set the UUT to 200 MHz, 5-kHz mod rate, 200-kHz DEV, INT AC FM. Set the 8901A to FM, +peak, 300-Hz HP, 15-kHz LP. Adjust R140 for a 8901A reading of 200 kHz  $\pm$ 1 kHz. Adjust R117 for symmetrical plus and minus readings about 200 kHz  $\pm$ 1 kHz. Repeat until both specs are met.
19. Set the UUT to 50 MHz, 5-kHz mod rate, 200-kHz dev, INT AC FM. Set the 8901A to FM, +peak, 300-Hz HP, 15-kHz LP. Adjust R139 for a 8901A reading of 200 kHz  $\pm$ 1 kHz. Adjust R115 for symmetrical plus and minus readings about 200 kHz  $\pm$ 1 kHz. Repeat until both specs are met.
20. Set the UUT to 800 MHz, 70-Hz MOD rate, 5-rad dev, INT AC FM. Set the 8901A to  $\phi$ M, +peak, 15 kHz LP (all other filters removed), Avg and 70.7%. Adjust R145 for 5 rad.

21. Set the UUT to 800 MHz, 10-kHz mod rate, 5-rad dEV, SPCL 721, INT AC FM. Set the 8901A to  $\phi$ M, +peak, 300 Hz HP, >20 kHz LP. Adjust C75 for a 8901A reading of 5 rad. Set the UUT to 1 kHz MOD rate. The 8901A reading must be 5 rad  $\pm$ 0.05 rad.
22. Set the UUT to 800 MHz, 70 Hz MOD rate, 5-rad dev, SPCL 721, INT AC FM. Set the 8901A to  $\phi$ M, +peak, no filters, Avg and 70.7%. Adjust R146 for 5 rad. Set UUT to SPCL 720.
23. Connect the 8840A to TP12 and adjust R49 to 0V dc. Connect the 8840A to TP9. Verify that the 8840A reads between -3V dc and +10V dc.
24. Set the UUT to SPCL 909, 800 MHz, -5 dBm, 10 Hz mod freq, 25 kHz FM dev, SPCL 711, SPCL 752. Set the spectrum analyzer to IP, center freq 800.06 MHz, span 100 kHz, ref level -5 dBm, resolution bandwidth 30 kHz, video bandwidth 30 kHz, sweep time 200 ms, log scale 6 dB, trigger free run.

Set the UUT to INT FM. Set analyzer to span 0 Hz, trigger video. Verify that the droop of the demodulated FM is less than 10%. Set the UUT to EXT DC FM. Verify that the droop of the demodulated dc FM is less than 2%.

25. Set the UUT to 800 MHz, 300-kHz dev, 1-kHz mod rate, EXT AC FM on. Connect the 8840A to TP12 and check that the 8840A reads 0V dc  $\pm$  200 mV dc.

Set the UUT to 200-kHz dev. Check that the 8840A reads 0V dc  $\pm$ 200 mV dc.

26. Set the UUT to 800 MHz, 10-kHz dev, 1-kHz mod rate, EXT AC FM. Place a 600 $\Omega$  load on the UUT EXT FM input. Connect the 1953A Counter to the UUT output, and set the 1953A to read 800 MHz with 1-Hz resolution.

Set the UUT to EXT DC FM. The front panel DC FM indicator should light within 1 second. The 1953A should read within 350 Hz of the 800-MHz ac FM frequency. Connect the 8840A to TP12. TP12 should read 0V dc. Connect the 8840A to J1-P3. The 8840A should read between 3V dc and 8V dc.

Set the UUT to AC FM. Repeat step 25 to verify the performance.

27. Set the UUT to 300-kHz dev. Set the UUT to EXT DC FM. The front panel DC FM indicator should illuminate within one second. The 1953A should read within 500 Hz of the 800-MHz ac FM frequency. Connect the 8840A to TP12. TP12 should read 0V dc. Connect the 8840A to J1-P3. The 8840A should read between 3V dc and 8V dc.

Set the UUT to AC FM. Repeat step 26 to verify the performance.

## Section 6F Internal Modulation Oscillator

### **MODULATION OSCILLATOR BLOCK DIAGRAM** **6F-1.**

Refer to the Modulation Oscillator Block Diagram (Figure 6F-1) to identify the major functional sections and follow the signal paths of the internal modulation oscillator.

### **INTERNAL MODULATION OSCILLATOR CIRCUIT DESCRIPTION** **6F-2.**

The modulation oscillator is configurable either as a direct digital synthesizer (DDS) or as a pulse generator. Both functions are implemented in a custom integrated circuit and are synthesized from the main reference frequency source of the instrument.

The A6 Mod Oscillator PCA provides two outputs:

- An internal modulation source (Int Mod)
- A modulation output source (Mod Out), available at the MOD OUTPUT BNC connector on the front panel.

All power, data, control, and clock signals are received by the Mod Oscillator PCA via a bus connector (J1) and clock connector (J2).

### **Direct Digital Synthesized Wave Generator** **6F-3.**

The direct digital synthesizer frequency is the modulation source for the internal AM, FM,  $\phi$ M, and pulse functions. It can be set from 0.1 Hz to 200 kHz with resolution of 0.1 Hz. The amplitude of the internal modulation source (Int Mod signal) is a leveled 1V pk, internally routed to the A33 Modulation Control PCA. The amplitude of the modulation output is controlled by a level dac. An algorithmic wave generation method provides a very accurate and stable oscillator signal source of high purity and low harmonic distortion.

Custom IC U1 acts as the wave generator by using external wave lookup table U2 and U3, and 12-bit wave reconstruction dac U7 and U9B. A discrete time sample method generates the various waves. A low-pass antialiasing filter made up of R6, R7, C13, C14, and L1 is required to reject the sampling frequency, the alias signals, and the out-of-band spurious signals from the output signal.

The amplitude of oscillation at the MOD OUTPUT connector is controlled by 12-bit multiplying dac U8 and U11A. This output level can be set between 0 and 4V pk, with 1-mV pk steps, into a 600-ohm load.

INTERNAL MODULATION OSCILLATOR

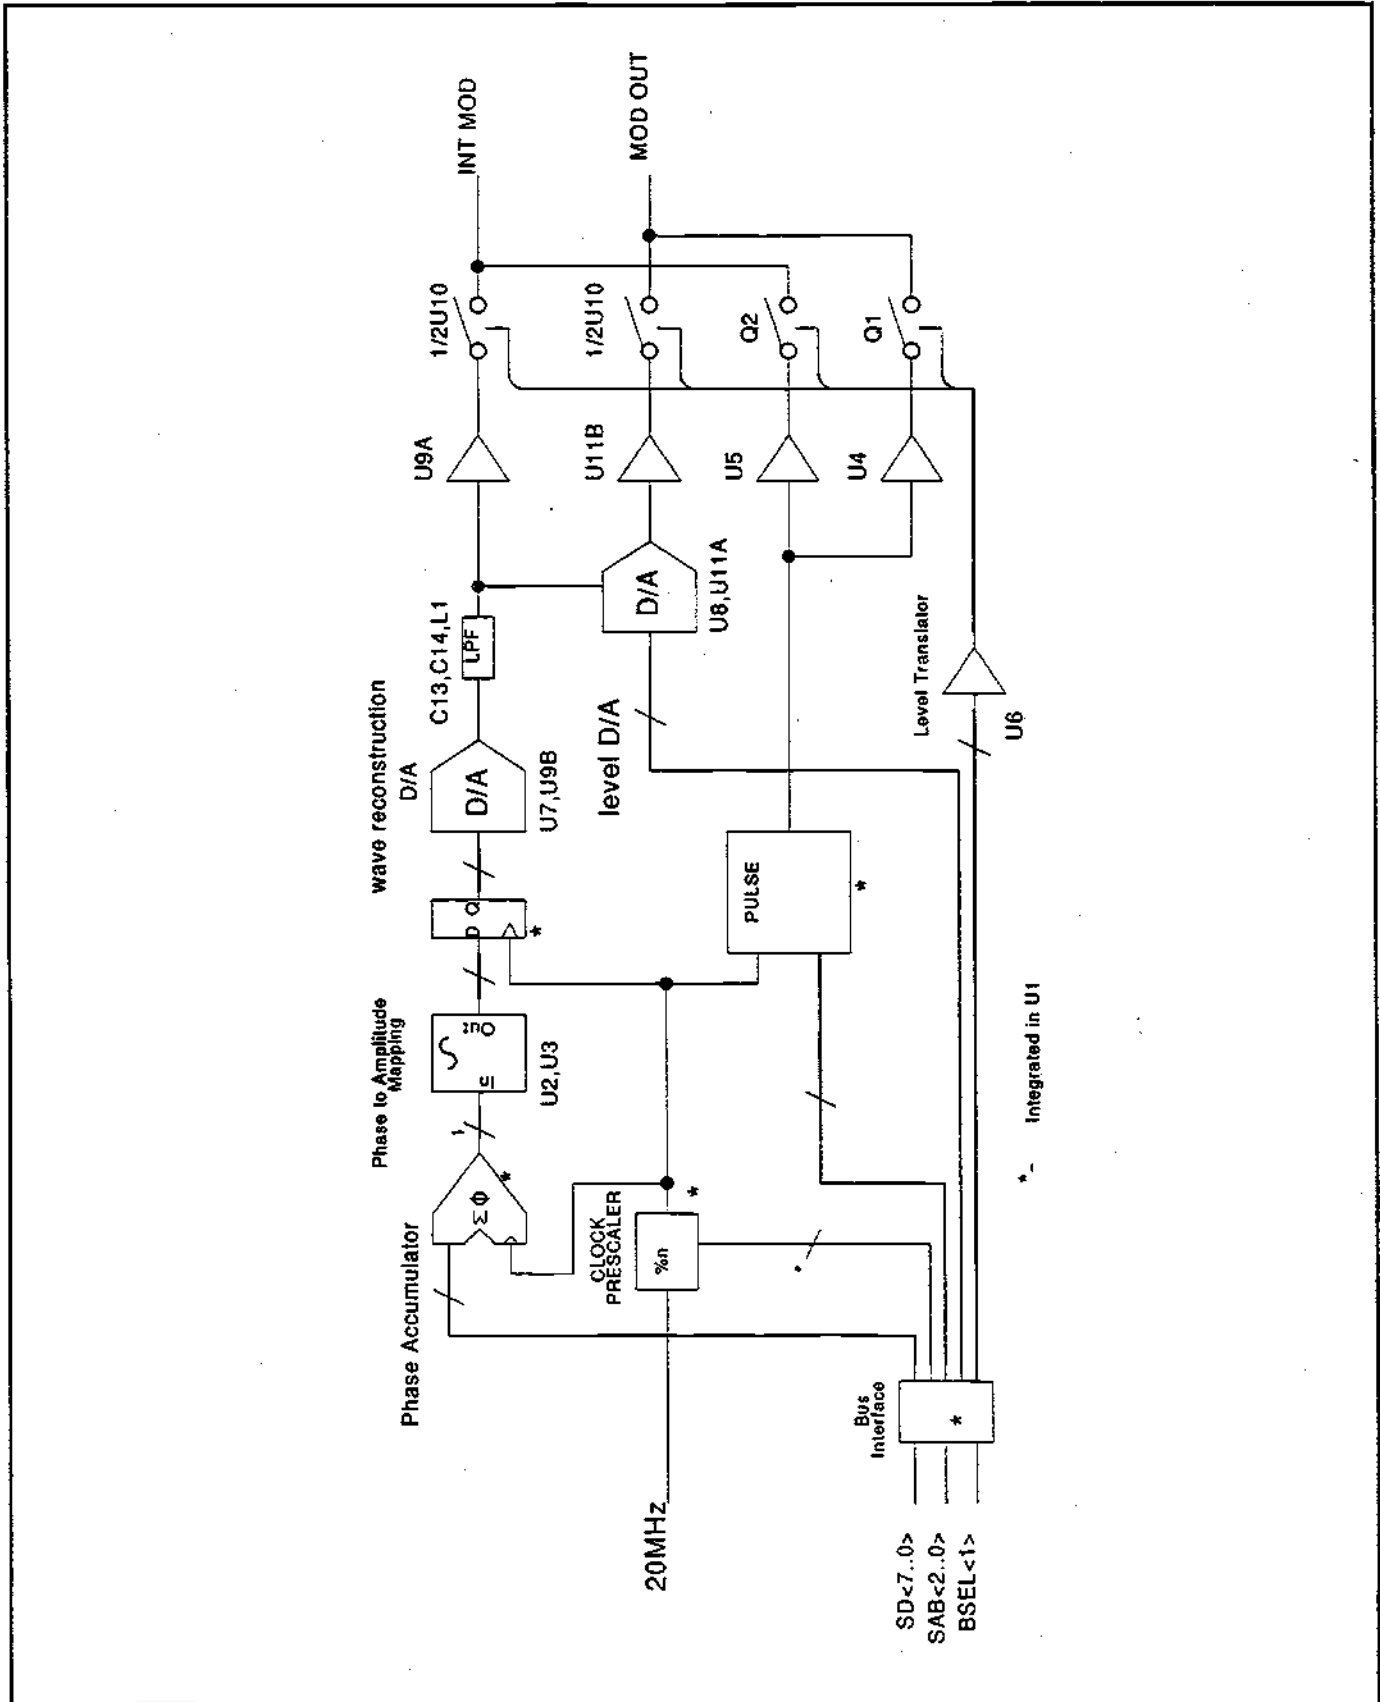

Figure 6F-1. Mod Oscillator Block Diagram

Waveform data is stored in EPROMS U2 and U3. Three control lines from U1 control waveform selection, allowing up to eight waveforms to be selected via a front panel special function. When you select a wave other than the sine wave, make sure you consider the low-pass filter cutoff frequency of 200 kHz. There will be a progressive deterioration of the fidelity of waves with increased frequency, depending on the wave shape selected. This relates to the higher frequency components of the waves other than the sine wave.

### Pulse Generator

6F-4.

The pulse generation mode is selected via the front panel or IEEE Special Function commands. The frequency of the pulse generator can be set from 10 Hz to 200 kHz. Frequency and pulse width are determined by numeric values written to the oscillator. The built-in pulse generator can be used as a modulation source for the internal AM, FM,  $\phi$ M, and pulse.

The pulse generator is also based on custom IC U1, which contains a programmable period and pulse width sections. Both the period and the pulse width can be set in increments of 100 ns. Internally, the pulse frequency is rounded and set to the nearest 100 ns period increment of the entered modulation frequency.

U4, U5, Q1, Q2, and their associated components condition the external and internal pulse signals. When in the pulse generation mode of operation, the internal pulse at Int Mod is preset to 1V pk via U5. U4 buffers the pulse output of U1 to provide Mod Out, which is fixed at 4.5V CMOS/TTL logic level. Both the frequency and the pulse width are set numerically through front panel entry or via IEEE commands. In pulse generation mode, Mod Out is terminated with a nominal 180 $\Omega$ .

To avoid the ambiguity of the pulse output from being set to a dc value, the software limits the pulse width to a value that is no wider than the set period minus 100 ns, and the software prevents the pulse width from being set narrower than 100 ns.

See the Special Function list in Appendix B for selections modulation oscillator modes of operations. The appropriate Special Functions allow the selection of direct digital synthesis, output waveform, pulse generator, and pulse width setting. Additionally, by selecting the appropriate special function code, you can enable MOD OUT to be continuously on (default) or to be turned on only during the selection of internal modulation.

### Signal Routing

6F-5.

The modulation oscillator selects the active outputs through six analog switches. Signals from U1 control the various switches that route the pulse generator and direct digital synthesizer output signals to the two outputs (Int Mod, Mod Out) of the A6 Modulation Oscillator PCA.

Switches S1 and S2 (associated with U9A, U6A, and U6B) facilitate the connection of the direct digital synthesizer to the internal modulation source (Int Mod).

Switches S3 and S4 (associated with U11B, U6C, and U6D) facilitate the connection of the direct digital synthesizer to the modulation output (Mod Out).

Switches S5 and S6 (associated with U4, U5, U6B, and U6D) facilitate the connection of the pulse generator to both the modulation output (Mod Out) and to the internal modulation source (Int Mod).

## MOD OSCILLATOR TROUBLESHOOTING AND ADJUSTMENTS

6F-6.

Since both the direct digital synthesizer and the pulse generator sections are clocked by the same clock, verify the 20 MHz input signal first. The amplitude of this wave should be at least 300 mV p-p. If this clock signal is absent, none of the functions on the assembly will operate.

### Direct Digital Synthesizer Troubleshooting

6F-7.

To troubleshoot the direct digital synthesizer (DDS), proceed as follows:

#### SETTING UP:

1. Select SPCL 909 to set the UUT to the preset default state. This sets the DDS to generate a sine wave.
2. Enable INT AM modulation.
3. Set MOD LEV to a modulation output level of 4V pk.
4. Enter MOD FREQ of 1 kHz.
5. Connect a 600Ω load at the MOD OUTPUT connector.

#### TEST PROCEDURE:

#### NOTE

*S1-S6 refers to analog switches on the A6 Mod Oscillator.*

1. Check U1 output clock CLKO at TP10. This logic level signal should be 3.33 MHz. If there is no signal at this point or if the frequency is wrong, either U1 is faulty, wrong data is written to it, or the 20-MHz signal is inadequate. If this signal is absent, the DDS sections will not operate.
2. Use an oscilloscope to verify that the most significant bit (MSB) of the phase accumulator (TP8) is at TTL level and is 1 kHz (the set modulation frequency). If the MSB is not as indicated, the U2 most significant lookup table, or the U1 phase accumulator section may have failed.
3. Use the oscilloscope to verify the presence of a 10V p-p ( $\pm 5\%$ ) sine wave at the output of the U7 wave reconstruction dac (TP2). If the sine wave is not present, suspect U7 and the dac output amplifier U9A, or wave tables U2 and U3. If the signal is not zero centered or the amplitude is in error, check R4 and R5, also verify 10V  $\pm 2\%$  at U7 pin 4.
4. Verify that a 4.77V p-p  $\pm 5\%$  sine wave is present at TP3. If the sine wave is not present, or is the wrong amplitude, check the 3-pole low-pass filter components R6, C13, C14, L1 and R7.
5. Enter MOD FREQ of 100 kHz.
6. Repeat step 4 above.
7. Enter MOD FREQ of 1 kHz.

8. Use an oscilloscope to check for a 2V p-p sine wave at TP4. Measure its amplitude with an ac voltmeter and verify that it is 0.7071V rms within  $\pm 0.1\%$  ( $\pm 0.7$  mV). If the sine wave is not present or is distorted, check S1 and S2 at U10, and check U9B and its associated components. If the amplitude is slightly off, recalibrate R9 using normal calibration procedures.
9. Use an oscilloscope to verify a 4.66V p-p ( $\pm 5\%$ ) sine wave signal at TP9, and check for visible distortions. If the sine wave is not present, is distorted, or is the wrong amplitude, check level dacs U8, and U11A.  
  
If U8 and U11A are OK, check for a failed U1, which would cause a write data error. If U1 is operating correctly, check for an interface bus fault.
10. Use an oscilloscope to verify a zero centered 8V p-p sine wave at TP5. If the signal is distorted, check U11B and associated resistors R11, R12, and R13 and switches S3 and S4. With an ac voltmeter, check for 2.8284V rms  $\pm 0.1\%$  ( $\pm 2.8$  mV). If the signal not within specifications, recalibrate R13 using normal calibration procedures.

### Pulse Generator Troubleshooting

6F-8.

To troubleshoot the pulse generator, proceed as follows:

#### SETTING UP:

1. Enter SPCL 758 to set the instrument to the preset default state.
2. Enter SPCL 741 to set the instrument to internal pulse operation.
3. Enable INT AM modulation.
4. Enter MOD FREQ of 10 kHz (100 us period).
5. Enter SPCL 759 to set the pulse width to 25  $\mu$ s.

#### TEST PROCEDURE:

#### NOTE

*Modulation level control has no effect in pulse mode.*

1. Verify a 10.0-MHz logic signal at TP10. If no signal is present at this point or the signal is the wrong frequency, either U1 has failed, a data write error has occurred, or the 20-MHz signal is inadequate.
2. Use an oscilloscope connected to TP11 to verify that the TTL-level pulse signal from U1 is 10 kHz with a positive pulse width of 25 us. If it is not, U1 may be faulty.
3. Use an oscilloscope to verify that the TTL-level pulse described in step 2 above is present at TP5.
4. Use an oscilloscope to observe TP4 and verify that the same pulse shape described in step 2 is zero centered with an amplitude of 2V  $\pm 10\%$  p-p. If either the amplitude or wave shape is incorrect, check U5 and associated resistors R22, R23, R24, and R25.

# Section 7

## Compensation Procedures

### INTRODUCTION

7-1.

The internal software compensation procedures generate the instrument-specific compensation data for the following assemblies:

- A3 Sunsynthesizer VCO
- A5 Coarse Loop VCO
- A9 Sum Loop VCO
- A31 Output
- A35 Attenuator/RPP

These procedures must be performed following any repair to the related assembly that affects the compensation. The procedures restore the operating specifications of the Signal Generator provided there are no remaining hardware failures. If the required adjustments exceed the procedure's adjustment limits, the Signal Generator needs to be repaired. Refer to Section 6, "Circuit Descriptions, Troubleshooting, and Alignment" for details. Section 6 explains the Module Exchange Program as well as component-level troubleshooting hints.

### LEVEL FLATNESS COMPENSATION

7-2.

The level flatness compensation procedures generate the instrument-specific compensation data for the A31 Output PCA and the A35 Attenuator/RPP Assembly.

Output flatness compensation corrects for frequency-dependent level flatness errors in the A31 Output PCA. The Output Flatness Compensation Procedure (also referred to as the Output Compensation Procedure) involves measuring the level error at up to 60 frequencies, from which correction factors are calculated and stored in the nonvolatile compensation memory on the A13 Controller PCA. When an RF frequency is programmed, the correction factors associated with the two nearest frequencies are interpolated to determine the applied level compensation.

The Output Compensation Procedure must be performed following any repair to the A31 Output PCA that affects the output flatness compensation. In addition, there is storage provided for alternate output compensation data that can be used to compensate for an external system without affecting the normal output compensation data. This alternate compensation data can be used to correct for level flatness errors at the output of an external amplifier or at the end of a length of cable. There is typically 1-dB of overrange which may be used for this purpose.

## COMPENSATION PROCEDURES

The Output Compensation Procedure requires the use of a power meter, or a measuring receiver in the power meter mode. The procedure can be performed from the front panel or remotely under the control of an IEEE-488 bus controller. It consists of the following steps:

1. Set the rear panel CAL|COMP switch to the 1 (on) position.
2. Connect the power meter sensor to the Signal Generator's RF output.
3. Initiate the compensation procedure.
4. Adjust the RF level until the power meter reading matches the displayed target level for every step in the procedure.
5. Store the updated compensation data.

Attenuator flatness compensation corrects for frequency-dependent level flatness errors in the Attenuator/RPP. The Attenuator Flatness Compensation Procedure (also referred to as the Attenuator Compensation Procedure) involves measuring the level error for each attenuator section at up to 29 frequencies, from which the correction factors are calculated. When an RF frequency or amplitude is programmed, the correction factors associated with the two nearest frequencies for the programmed RF level are interpolated to determine the applied level compensation. The attenuator compensation procedure must be performed following a repair to the Attenuator/RPP that affects the attenuator flatness compensation.

The Attenuator Flatness Compensation Procedure must be performed using a measuring receiver in order to guarantee the level flatness specification. An alternate procedure may be performed using a power meter, but this procedure does not guarantee compliance with the flatness specification. The procedure can be performed from the front panel or remotely under the control of an IEEE-488 bus controller. It consists of the following steps:

1. Set the rear panel CAL|COMP switch to the 1 (on) position.
2. Lock the measuring receiver and Signal Generator references together.
3. Connect the measuring receiver sensor module to the Signal Generator's RF output.
4. Initiate the compensation procedure.
5. For each of the frequency steps in the procedure, tune the measuring receiver to match the Signal Generator frequency. For the first three level settings at the frequency step, measure the RF level using the power meter mode of the measuring receiver. Adjust the RF level of the Signal Generator until the measuring receiver reading matches the displayed target level.
6. For the remaining level settings at the frequency step, measure the level in tuned RF mode. If the frequency is below 2.5 MHz, the measuring receiver must be used in power meter mode. Irrespective of the measurement mode, adjust the Signal Generator level until the measuring receiver reading matches the displayed target level.

7. If the frequency step in the procedure is above a specified "break frequency," the effects of VSWR are significant in the level measurement. Thus, additional level measurements and adjustments must be made using combinations of attenuators to reduce VSWR effects. In making these measurements, care must be taken to ensure that the measuring receiver calibration is transferred correctly through its level bands as successively lower RF levels are measured.
8. Repeat steps 5, 6, and 7 for every frequency step in the procedure.
9. Store the updated compensation data.

### **Level Flatness Compensation Accuracy Notes**

7-3.

The level compensation procedures restore the operating specifications of the Signal Generator. Performance can be verified using the High-Level Accuracy Test, Mid-Level Accuracy Test, and Low-Level Accuracy Test, or the Alternate Level Accuracy Test, all in Section 3.

Failure to observe the following guidelines may result in less than optimal or out-of-specification operation:

- The measuring receiver and sensor module must be calibrated and operated according to its manufacturer's instructions. The calibrated measuring receiver and sensor module combination must yield 0.05-dB measurement accuracy or better.
- The power meter and sensor must be calibrated and operated according to its manufacturer's instructions. The frequency-dependent power meter calibration factors must be set for each frequency. The calibrated power meter/sensor combination must yield 0.05-dB measurement accuracy or better. It must be zeroed whenever a procedure calls for this to be done.
- Both the output and attenuator level measurements must be made with the measuring receiver sensor module connected at the RF OUTPUT connector. Do not use a length of cable between the RF OUTPUT connector and the power sensor unless you are intentionally correcting for losses in the cable.

### **Level Flatness Compensation Limits**

7-4.

The maximum compensation allowed for the output section is 4.0 dB. The maximum compensation allowed for the 6082A attenuator section is 8.0 dB.

The measured output corrections are normalized before being stored to remove any fixed level offsets. The 4.0-dB limit is checked after the measurements are normalized so it is possible to make adjustments greater than 4.0 dB as long as the range of values does not exceed 4.0 dB. The measured data cannot be stored if the limit is exceeded. Any offset removed by the normalization process must be eliminated by adjusting the main level adjustment potentiometer R20, on the A33 Modulation Control PCA, after the procedure is complete.

## COMPENSATION PROCEDURES

The maximum output compensation allocation allows approximately 1 dB of margin over typical usage. This additional range can be used when compensating an external system. If measurements taken at the front panel RF connector exceed the maximum limit, suspect a faulty or misaligned output section. Refer to the related paragraphs in Section 6 of this manual.

The measured attenuator corrections are normalized then summed into all programmable attenuator combinations before being stored. The compensation limit of 8.0 dB is the maximum allowed for any combination of attenuators. This makes it difficult to tell if the maximum allocation will be exceeded until all measurements have been completed. The measured data cannot be stored if the maximum allocation has been exceeded for any combination of attenuators. If the maximum allocation has been exceeded, suspect a faulty attenuator section. Refer to the related paragraphs in Section 6 of this manual.

If the output and attenuator circuits are operating correctly but the maximum compensation allocations have been violated, and a level flatness compensation procedure has been previously performed, there may be excessive mixing of the output and attenuator compensation data. Refer to "Level Compensation Data Mixing", below.

### Level Compensation Data Mixing

7-5.

The A31 Output and A35 Attenuator assemblies are compensated separately during the manufacturing process. Upon receipt from the Fluke factory, the output compensation data only corrects for errors in the output circuitry, and the attenuator compensation data only corrects for errors in the attenuator circuitry.

Measurements made during the user output and attenuator compensation procedures are made at the front panel RF OUTPUT connector. The measured level includes errors from both the output and attenuator circuits. Therefore, performing an output compensation procedure may correct for some errors in the attenuator circuitry, and performing an attenuator procedure may correct for errors in the output circuitry.

The resultant mixing of the correction data usually has a negligible effect. Mixing of this data may cause problems if an Output or Attenuator Compensation Procedure is performed improperly, or is used to compensate misaligned hardware. As a result, there may be measurement points that contain excessively large or unusually small correction values. There may be sufficient correction range to complete the procedure successfully. However, subsequent compensation procedures may fail.

For example, assume that at 2100 MHz, the output circuitry requires 4 dB of correction and the attenuator circuitry requires 6 dB of correction. An Output Compensation Procedure is performed improperly so that a 1-dB correction is stored at 1056 MHz instead of the expected 4 dB correction, resulting in a 3 dB error. The 4-dB limit for the output procedure is not violated so, the procedure completes successfully. At a later time, an Attenuator Compensation Procedure is attempted. To reach the target level at 2100 MHz, the attenuator procedure must apply the expected 6 dB of correction plus an additional 3 dB to correct for the error in the output data. The 8-dB limit for the 6082A attenuator procedure is violated and the data cannot be stored even though both the output and attenuator circuits are operating properly.

Errors due to mixing the correction data will rarely occur when reasonable care is exercised. If the problem does arise, the Output Compensation Procedure with Default Attenuator Data can be used to reduce the mixing. Refer to "Front Panel Output Compensation with Default Attenuator Data" later in this section.

The output and attenuator module exchange (MEC) assemblies are compensated separately during the manufacturing process. If the current output and attenuator data was generated by the Fluke Factory, an output or attenuator module exchange PROM can be uploaded without performing any compensation procedures. If an output compensation procedure was performed prior to the installation of an attenuator MEC assembly, it may be necessary to perform an output compensation procedure. Alternately, if an attenuator compensation procedure was performed prior to the installation of an output MEC assembly, it may be necessary to perform an attenuator compensation procedure.

To determine the data origin of the compensation memory, press **SPL** **0** **5**.

If all data was generated by the Fluke factory, the status code 00 is displayed. If any of the data was generated in any other way, a status code or list of status codes are displayed. Press **STATUS** to scroll through the list if there are more than three status codes. Refer to Appendix F, "Compensation Memory Status Codes".

### Front Panel Output Flatness Compensation Procedure

7-6.

- Adjustment Range: up to 4.00 dB
- Adjustment Resolution: 0.01 dB
- Target Level: 10.0 dBm
- Number of Measurement Steps: One per frequency (up to 60 frequencies).
- External Equipment: RF Power Meter (HP 436A or equivalent) and Power Sensor (HP 8482A or equivalent)

See Table 7-1 for front panel controls for Output Flatness Compensation Procedure. The Front Panel Output Flatness Compensation Procedure is initiated by pressing

**SPL** **9** **8** **1**.

The target RF level of 10 dBm is displayed in the MODULATION field, the RF frequency is displayed in the FREQUENCY field and the level adjustment is displayed in the AMPLITUDE field. The frequencies may vary from instrument to instrument.

The RF level is adjusted using the edit knob until the measured level at the RF output is 10 dBm at each of up to 60 frequencies. This procedure typically takes 15 minutes to perform. The Signal Generator must be operated at room temperature for at least one hour with the module plate covers in place before performing this procedure.

Proceed as follows to execute the Front Panel Output Flatness Compensation Procedure:

1. Press **SPL** **0** **1**, then program 350 MHz and +9 dBm.

## COMPENSATION PROCEDURES

Table 7-1. Front Panel Controls for Output Flatness Compensation Procedure

CONTROLS	FUNCTION AND DESCRIPTION
 	BRIGHT DIGIT EDITING
KNOB	Turn edit knob to increment or decrement the level adjustment. Use the left/right arrow keys to move the bright digit.
	RF ON/OFF Toggles the RF output on/off.
	OVERRANGE/UNCAL or REJECTED ENTRY STATUS Normally displays the overrange/uncal status. Displays the rejected entry status code if there is a rejected entry.
	STORE MEASURED DATA Press once, the prompt "Sto ?" is displayed. Press again to store the data. "-- Sto --" is displayed for approximately 10 seconds while the data is stored. Attempts to store the data before all steps have been measured will be rejected with error code 92. Attempts to store data with out of limit conditions will be rejected with error code 93. Press any other key to cancel the store operation and resume the procedure.
<b>CAUTION</b>  Do not turn the POWER switch off or change the CAL COMP switch until the store operation is complete. Doing so could damage the contents of the compensation memory.	
	ABORT THE PROCEDURE Press the key once, the prompt "Clr ?" is displayed. Press the key again to abort the procedure. "-- Clr --" is displayed to confirm the selection. All measured data is discarded and the previous instrument state is restored. Press any other key to resume the procedure.

2. Disable the Signal Generator's RF output, and connect the power sensor to the RF output.
3. Zero the power meter and select the power meter calibration factor. Enable the RF output.
4. Measure the RF level.

If it is more than +9.0 dBm  $\pm$  1.0 dB, the A31 Output PCA or A35 Attenuator/RPP Assembly is not operating correctly. Refer to Section 6 in this manual for troubleshooting and repair information.

5. Set the rear panel CAL|COMP switch to the 1 (on) position. Verify that the CAL and COMP annunciators on the front panel are flashing.

**CAUTION**

Do not turn the power off while the CAL|COMP switch is set on. The CAL|COMP switch protects the compensation memory from accidental damage.

6. Press **SPCL** **9** **8** **1** to initiate the Output Compensation Procedure. Verify that COMP and OUT annunciators are lit.
7. Set the CAL factor on the power meter for the displayed frequency.
8. Use the edit knob to adjust the level until the the power meter reads 10 dBm.
9. Press STEP **▲** to go to the next frequency step.
10. Repeat steps 7 through 9 until the last frequency step has been completed (a frequency of 2100 MHz). At this point, pressing the STEP **▲** key causes the message "End" to be displayed.
11. Press the **STO** key twice to store the data.

**NOTE**

*If the store operation is rejected (flashing "—Sto—"), press **STATUS** to determine the cause of the rejected entry. Refer to the list of rejected entry error codes in Appendix C. Also refer to "Level Flatness Compensation Limits," "Level Compensation Data Mixing," and "Het Band Level Adjustment" in this section.*

12. Zero the RF Level Closed-Case Calibration Factor to provide maximum adjustment range. This step may be performed at the beginning of the procedure between steps 5 and 6 if desired. However, doing so may introduce a fixed offset which must be compensated for at every measurement step. To zero the RF Level Calibration Factor:
  - a. Enter **SPCL** **9** **9** **3**
  - b. Use the edit knob to adjust the calibration factor until it reads 0.00 dB.
  - c. Press **STO** twice to store the new calibration factor.
13. Set the rear panel CAL|COMP switch to the 0 (off) position. Verify that the CAL and COMP annunciators on the front panel are not flashing.
14. Remove the bottom instrument cover and the RF level adjustment access screw labeled A33R20 from the bottom module plate cover.
15. Press **SPCL** **0** **1**, then program 350 MHz and +9 dBm.
16. Disable the Signal Generator RF output, zero the power meter, then enable the RF output. Select the power meter calibration factor.

## COMPENSATION PROCEDURES

17. Adjust the RF level adjustment at A33R20 for a reading of exactly +9 dBm on the power meter.
18. Replace the RF level adjustment access screw and the bottom instrument cover.

### Het Band Level Adjustment

7-7.

A store operation at the end of an Output Compensation procedure can fail because the Het Band level is not adjusted properly. When a store operation is rejected with error 93 (too much correction), exit the procedure and perform the following steps.

1. Enter    , and note the frequency displayed in the FREQUENCY field, and the amplitude adjustment displayed in the AMPLITUDE field.
2. Program the 6082A to the frequency displayed in the FREQUENCY field and +10.0 dBm.
3. Program the power meter with the calibration factor that corresponds with the frequency displayed in the FREQUENCY field.
4. Adjust the Het Level Adjustment A31R96 by the amount displayed in the AMPLITUDE field.
5. Perform the output compensation procedure again.

### Compensating Level Flatness Errors in an External System

7-8.

The Output Flatness Compensation Procedure can be used to correct for level flatness errors in an external system that is connected to the signal generator's RF output. Compensation for losses attributable to the external system can be applied up to the specified limits of the Output Compensation Procedure. There is typically 1 dB of overrange which may be used for this purpose.

Proceed as follows to compensate an external system:

1. Connect the input of external system to the RF output of the 6082A and connect the power meter sensor to the RF output of the external system.
2. Select the alternate output compensation data by entering    .
3. Perform the Output Flatness Compensation Procedure as described earlier in this section.

#### NOTE

*It is not necessary to set the CAL|COMP switch to the 1 (on) position as specified in the Output Flatness Compensation Procedure when the alternate output compensation data has been selected by Special Function 931.*

While Special Function 931 is enabled, compensation data generated by the Output Flatness Compensation Procedure will be stored in a separate location, leaving the normal output compensation data unchanged. Subsequent frequency programming operations will use the alternate output compensation data. Enter Special Function 930 to select the normal output compensation data.

After the alternate output compensation data has been generated, Special functions 930 and 931 can be used to switch between the normal and alternate data as desired. The Special Function selection is retained while the instrument power is off and is not affected by instrument preset or memory recall operations.

**NOTE**

*The alternate output compensation data is set to 0 dB of correction when the 6082A is manufactured. If any alternate data are stored, they are set to 0 dB if the memory erase function (     ) is executed. See Section 4D of the Operator Manual for more information on the memory erase function.*

**Front Panel Output Compensation with Default Attenuator Data 7-9.**

The Output Compensation Procedure with Default Attenuator Data may be used to reduce the mixing of the output and attenuator compensation data. In this procedure, the compensation data for the A31 Output PCA is generated while the attenuator circuitry is compensated using the last Fluke Factory or module exchange data for the attenuator circuit.

The default attenuator data may not accurately characterize the current state of the attenuator circuitry. However, it will have a typical distribution and should allow the procedure to be performed successfully regardless of the amount of mixing in the normal compensation data. Upon completion, the Attenuator Compensation Procedure must be performed to restore the instrument specifications.

The process is identical to the Output Compensation Procedure except that it initiated by Special Function 983. Refer to "Front Panel Output Flatness Compensation Procedure," earlier in this section.

**Front Panel Attenuator Flatness Compensation Procedure 7-10.**

- Adjustment Range: up to 8.00 dB
- Adjustment Resolution: 0.01 dB
- Target Levels: 10.0 dBm, 4.0 dBm, -2.0 dBm, -14.0 dBm, 38.0 dBm, -44.0 dBm, -50.0 dBm, -62.0 dBm
- Number of Frequency Steps: Up to 29
- Number of Measurement Steps: 8 per frequency ( $f_c < 1700$  MHz typical), 14 per frequency ( $f_c \geq 1700$  MHz typical)
- External Equipment: RF Measuring Receiver (HP 8902 or equivalent), Microwave Converter (HP 11793 or equivalent), and Local Oscillator (Fluke 6082A or equivalent)

## COMPENSATION PROCEDURES

The Front Panel Attenuator Flatness Compensation Procedure is initiated by the following key sequence: **SPC** **9** **8** **2**

The target RF level is displayed in the MODULATION field, the RF frequency is displayed in the FREQUENCY field and the level adjustment is displayed in the AMPLITUDE field. The frequencies may vary from instrument to instrument.

The RF level is adjusted using the edit knob until the measured level at the RF output matches the target level. This sequence is repeated for each attenuator section (the through-path, each of seven attenuators) at up to 29 frequencies. Additionally, six combinations of attenuators are measured for frequencies typically above 1700 MHz.

### NOTE

*The Front Panel Attenuator Compensation Procedure may take up to two and one half hours to perform. Exercise care to ensure that the measured value matches the target value for every measurement step. Failure to do so may result in not meeting performance specifications.*

The target RF output level displayed in the MODULATION field is determined by the attenuator section(s) to be measured. Table 7-2 lists the target levels.

Table 7-3 summarizes the operation of the front panel keys used during the Front Panel Attenuator Flatness Compensation Procedure. All other keys are ignored.

Table 7-2. Attenuator Target Levels

ATTENUATOR	TARGET LEVEL
Through-path	10 dBm
6 dB	4 dBm
12 dB	-2 dBm
24a	-14 dBm
24b	-14 dBm
24c	-14 dBm
24d	-14 dBm
24e	-14 dBm
24a + 24b	-38 dBm
24a + 24b + 6 dB	-44 dBm
24a + 24b + 12 dB	-50 dBm
24a + 24b + 24c	-62 dBm
24a + 24b + 24d	-62 dBm
24a + 24b + 24e	-62 dBm

Table 7-3. Front Panel Controls for Attenuator Flatness Compensation Procedure

CONTROLS	FUNCTION AND DESCRIPTION
◀ ▶	BRIGHT DIGIT EDITING
KNOB	Turn edit knob to increment or decrement the level adjustment. Use the left/right arrow keys to move the bright digit.
ON/OFF	RF ON/OFF Toggles the RF output on/off.
STATUS	OVERRANGE/UNCAL or REJECTED ENTRY STATUS Normally displays the overrange/uncal status. Displays the rejected entry status code if there is a rejected entry.
STO	STORE MEASURED DATA Press the key once, the prompt "Sto ?" is displayed. Press the key again to store the data. "-- Sto --" is displayed for approximately 30 seconds while the data is stored. Attempts to store the data before all steps have been measured will be rejected with error code 92. Attempts to store data with out of limit conditions will be rejected with error code 93. Press any other key to cancel the store operation and resume the procedure.
<b>CAUTION</b> Do not turn the POWER switch off or change the CAL COMP switch until the store operation is complete. Doing so could damage the contents of the compensation memory.	
CLR LCL	ABORT THE PROCEDURE Press the key once, the prompt "Clr ?" is displayed. Press the key again to abort the procedure. "-- Clr --" is displayed to confirm the selection. All measured data is discarded and the previous instrument state is restored. Press any other key to resume the procedure.

**NOTE**

*The 6082A rear panel REF switch must be set to EXT, and the external reference input must be connected to the measuring receiver REF OUT connector. The Local Oscillator Reference must likewise be connected to the measuring receiver REF OUT connector.*

The Signal Generator must be operated at room temperature for at least one hour with the module plate covers in place before performing this compensation procedure. Proceed as follows to execute the Front Panel Attenuator Flatness Compensation Procedure:

1. Press **SPCL** **0** **1** , then program 1 MHz, +10.0 dBm, and **SPCL** **9** **2** **2** . Note that the STATUS annunciator is lit. Press **STATUS** , status code 201 (Level Correction Disabled) should be displayed.
2. Disable the Signal Generator's RF output and connect the sensor module to the RF output.

## COMPENSATION PROCEDURES

3. Tune the measuring receiver to 1 Mhz, select the power meter mode, and zero the measuring receiver. Enable the RF output.
4. Measure the RF level. If it is more than  $+10.0 \text{ dBm} \pm 0.5 \text{ dB}$ , the A31 Output PCA or A21 Attenuator/RPP Assembly is not operating correctly. Refer to Section 6 in this manual for troubleshooting and repair information.
5. Disconnect the sensor lead from the RF input to the measuring receiver, and reconnect it to the RF input of the microwave converter. Connect the IF Output from the microwave converter to the RF input of the measuring receiver. See Figure 7-1 for the interconnections.

Figure 7-1. Attenuator Flatness Compensation Test Setup

**CAUTION**

The Signal Generator, microwave converter, local oscillator, and measuring receiver must remain connected throughout the entire procedure.

6. Program the Local Oscillator to 1300 MHz and 1 dBm. Connect the Local Oscillator RF Output to the Microwave Converter LO input.

**CAUTION**

Do not program the LO level above 1.0 dBm. Damage to the measuring receiver or microwave converter may result if higher levels are programmed.

7. Set the rear panel CAL|COMP switch to the 1 (on) position. Verify that the CAL and COMP annunciators on the front panel are flashing.

**CAUTION**

Do not turn the power off while the CAL|COMP switch is set on. The CAL|COMP switch protects the compensation memory from accidental damage.

6. Press **SPL** **8** **8** **2** to initiate the Attenuator Flatness Compensation Procedure. Verify that the COMP and ATT annunciators are lit.
7. Do the following step a but not b for frequencies below 1300 MHz. Do the following step b but not a for frequencies above 1300 MHz.
  - a. For frequencies below 1300 MHz the microwave converter is not used. Tune the measuring receiver to the displayed frequency and go to step 8.
  - b. For frequencies above 1300 MHz, the microwave converter must be used to tune the measuring receiver. In this case, the external LO mixes with the Signal Generator output to generate a difference frequency which is input to the measuring receiver. For the HP8902, do this as follows:
    1. Press **2** **7** **.** **0** **SPL** on the HP8902. This clears any previous frequency offset entries.
    2. Press **2** **7** **.** **3** **SPL** on the HP8902. This enables the frequency offset mode. Note that the f OFS annunciator is lit on the HP8902. Program the LO to the offset frequency, determined by the value of the displayed frequency on the Signal Generator:
      - Below 1900 MHz, offset frequency = displayed frequency + 120.53 MHz
      - Above 1900 MHz, offset frequency = displayed frequency - 120.53 MHz
    3. Enter the offset frequency on the HP8902. Next, enter the displayed Signal Generator frequency on the HP8902. The measuring receiver is now tuned.

## COMPENSATION PROCEDURES

8. For the first target level (10 dBm) at the tuned frequency, select the power meter mode of the measuring receiver. Zero the measuring receiver.
9. Use the edit knob to adjust the level until the measuring receiver reading matches the target level.
10. Press STEP  to go to the next measurement target level. For this level (4 dBm) and the following target level (-2 dBm) use the measuring receiver in the power meter mode and repeat the adjustment described in step 8. Note that for levels below 0 dBm, the level reading on the measuring receiver in power meter mode does not respond instantaneously to changes in the Signal Generator level and when finally settled, the receiver may have +0.01 dB jitter.
11. After completing the measurement and adjustment of the 10, 4, and -2 dBm levels, press STEP  to go to the next measurement target level (first of five -14 dBm levels). For this level and all subsequent level measurements at this frequency, the measuring receiver must be operated in tuned RF mode (unless the displayed frequency is less than 2.5 MHz, in which case the remaining level measurements must be made in the power meter mode). This requires that you transfer the calibration across the level bands of the measuring receiver. The measuring receiver indicates a need to do this by lighting a RECAL annunciator; the transfer is accomplished by pressing the CALIBRATE button on the front panel of the measuring receiver. When the transfer is complete, the RECAL annunciator turns off. You should always press CALIBRATE after entering the tuned RF mode, as the RECAL annunciator may not light above 1300 MHz.

### NOTE

*Details of the measuring receiver recalibration process are beyond the scope of this procedure. Refer to the measuring receiver operator manual for this information.*

12. Use the edit knob to adjust the level until the measuring receiver reading matches the target level. Press STEP , and repeat the adjustment for the remaining four -14 dBm target levels.
13. If the displayed frequency is above the break frequency (typically 1700 MHz) level measurements and adjustments must be performed for six additional target levels (-38 dBm, -44 dBm, -50 dBm, and three at -62 dBm). These levels are measured in the tuned RF mode, using the edit knob to adjust the level, and the STEP  to advance the next target level. Again, you should watch for the RECAL annunciator on the measuring receiver, and press the CALIBRATE button when it appears.

### NOTE

*Above 1300 MHz, the RECAL annunciator may not appear as frequently since the microwave converter outputs a constant IF frequency for all Signal Generator frequencies above 1300 MHz. However, it is advisable that you press the CALIBRATE button whenever you see that level readings do not stabilize within 20 seconds.*

14. On some occasions, when attempting measure target power levels that are near the lower end measuring receiver's level band breaks, the measuring receiver may become uncalibrated (UNCAL annunciator is lit). This is usually due to compound effects of losses in the measurement path. To recalibrate the measuring receiver under these circumstances, it is necessary to boost the 6082A target level so that it can be measured in the desired band. To do this, use the edit knob to adjust the level up on the Signal Generator until the UNCAL and the RECAL annunciators go out. Then, use the edit knob to lower the signal level until the RECAL annunciator is lit on the measuring receiver. At this point, perform the measuring receiver recalibration as described in step 12.
15. Repeat steps 7 through 14 until the last step (third -62 dBm target level at frequency of 2100 MHz) has been completed. At this point, pressing the STEP  key causes the message "End" to appear on the display.
16. Press the  key twice to store the data.

## NOTE

*If the store operation is rejected (flashing "—Sto—"), press  to determine the cause of the rejected entry. Refer to the list of rejected entry error codes in Appendix C. Also refer to "Level Flatness Compensation Limits" and "Level Compensation Data Mixing," earlier in this section.*

17. Zero the RF Level Closed-Case Calibration Factor to provide maximum adjustment range. This step may be performed at the beginning of the procedure between steps 5 and 6 if desired. However, doing so may introduce a fixed offset which must be compensated for at every measurement step. To zero the RF Level Calibration Factor:
  - a. Enter    
  - b. Use the edit knob to adjust the calibration factor until it reads 0.00 dB.
  - c. Press  twice to store the new calibration factor.
18. Set the rear panel CAL|COMP switch to the 0 (off) position. Verify that the CAL and COMP annunciators on the front panel are not flashing.
19. Remove the bottom instrument cover and the RF level adjustment access screw labeled A33R20 from the bottom module plate cover.
20. Program   , 350 MHz and +9.0 dBm
21. Tune the measuring receiver to 350 MHz, disable the RF output, select the power meter mode, zero the measuring receiver, then enable the RF output.
22. Adjust RF level adjustment at A33R20 for a reading of exactly +9 dBm on the measuring receiver.
23. Replace the RF level adjustment access screw, and the instrument bottom cover.

**Front Panel Attenuator Flatness Compensation Procedure Using Power Meter**

7-11.

- Adjustment Range: up to 8.00 dB
- Adjustment Resolution: 0.01 dB
- Target Levels: 10.0 dBm, 4.0 dBm, -2.0 dBm, -14.0 dBm
- Number of Measurement Steps: 8 per frequency (up to 29 frequencies).
- External Equipment: RF Power Meter (HP 436A or equivalent) and Power Sensor (HP 8482A or equivalent)

*NOTE*

*Use of this procedure does not guarantee compliance with the 6082A level accuracy specification over temperature. For the best obtainable results, use the procedure under paragraph 7-9. The following procedure gives good results with much less test equipment and in less time.*

The Front Panel Attenuator Flatness Compensation Procedure Using Power Meter is initiated by the following key sequence:

The target RF level is displayed in the MODULATION field, the RF frequency is displayed in the FREQUENCY field and the level adjustment is displayed in the AMPLITUDE field. The frequencies may vary from instrument to instrument.

The RF level is adjusted using the edit knob until the measured level at the RF output matches the target level. This sequence is repeated for each attenuator section (seven attenuators plus the through-path) at up to 29 frequencies.

*NOTE*

*This procedure may take up to 1 hour to perform. Exercise care to ensure that the measured value matches the target value for every measurement step. Failure to do so may result in poor signal generator performance.*

The target RF output level displayed in the MODULATION field is determined by the attenuator section being measured. Table 7-4 lists the target levels.

Table 7-3 summarizes the operation of the front panel keys used during the Front Panel Attenuator Flatness Compensation Procedure. All other keys are ignored.

**Table 7-4. Attenuator Target Levels (Power Meter Procedure)**

ATTENUATOR	TARGET LEVEL
Through-path	10 dBm
6 dB	4 dBm
12 dB	-2 dBm
24a	-14 dBm
24b	-14 dBm
24c	-14 dBm
24d	-14 dBm
24e	-14 dBm

The Signal Generator must be operated at room temperature for at least one hour with the module plate covers in place before performing this procedure. Proceed as follows to execute the Front Panel Attenuator Flatness Compensation Procedure Using Power Meter:

1. Press **SPCL** **0** **1**, then program 1 MHz, +10.0 dBm, and **SPCL** **9** **2** **2**.
2. Zero the power meter and select the power meter calibration factor.
3. Connect the power sensor to the Signal Generator's RF output.
4. Measure the RF level. If it is more than +10.0 dBm  $\pm 0.5$  dB, the A31 Output PCA or A21 Attenuator/RPP Assembly is not operating correctly. Refer to Section 6 in this manual for troubleshooting and repair information.
5. Set the rear panel CAL|COMP switch to the 1 (on) position. Verify that the CAL and COMP annunciators on the front panel are flashing.

**CAUTION**

Do not turn the power off while the CAL|COMP switch is set on. The CAL|COMP switch protects the compensation memory from accidental damage.

6. Press **SPCL** **9** **8** **8** to initiate the Attenuator Flatness Compensation Procedure. Verify that the COMP and ATT annunciators are lit.
7. Disable the RF output, zero the power meter, then enable the RF output.
8. Set the frequency dependent CAL factor on the power meter at each new frequency (target level of 10 dBm).
9. Use the edit knob to adjust the level until the power meter reading matches the target level.
10. Press STEP **▲** to go to the next measurement step.
11. For the first 24-dB attenuator at each frequency (target level of -14 dBm), the power meter must be zeroed.
12. Repeat steps 8 through 11 until the last measurement step (fifth 24-dB attenuator at frequency of 2100 MHz has been measured. At this point, pressing the STEP **▲** key causes the message "End" to be displayed.
13. Press the **STO** key twice to store the data.

**NOTE**

If the store operation is rejected (flashing "—Sto—"), press **STATUS** to determine the cause of the rejected entry. Refer to the list of rejected entry error codes in Appendix C. Also refer to "Level Flatness Compensation Limits" and "Level Compensation Data Mixing," earlier in this section.

## COMPENSATION PROCEDURES

14. Zero the RF Level Closed-Case Calibration Factor to provide maximum adjustment range. This step may be performed at the beginning of the procedure between steps 5 and 6 if desired. However, doing so may introduce a fixed offset which must be compensated for at every measurement step. To zero the RF Level Calibration Factor:
  - a. Enter
  - b. Use the edit knob to adjust the calibration factor until it reads 0.00 dB.
  - c. Press  twice to store the new calibration factor.
15. Set the rear panel CAL|COMP switch to the 0 (off) position. Verify that the CAL and COMP annunciators on the front panel are not flashing.
16. Remove the bottom instrument cover and the RF level adjustment access screw labeled A33R20 from the bottom module plate cover.
17. Program   , 350 MHz and +9.0 dBm.
18. Disable the RF output, zero the power meter, then enable the RF output. Select the power meter calibration factor.
19. Adjust RF level adjustment at A33R20 for a reading of exactly +9 dBm on the power meter.
20. Replace the RF level adjustment access screw, and the instrument bottom cover.

## REMOTE LEVEL FLATNESS COMPENSATION PROCEDURES

7-12.

The remote level compensation procedures allow the output and attenuator compensation data to be generated in a totally automated station. The sole function of the controller software is to obtain valid readings from the measurement equipment and convert them into a format understood by the 6082A. It must ensure that every reading is settled and valid before sending it to the 6082A.

### Remote Output Compensation Procedure

7-13.

The structure of an output flatness compensation program is outlined in Figure 7-2. A complete listing of a program that runs on a Fluke 1722A controller is in Appendix G.

The programming commands used in a remote output compensation procedure are listed in Table 7-5. Refer to Section 5B in the 6080A/82A Operator Manual for complete syntax descriptions of each command.

The desired output compensation procedure is initiated with the command COMP\_OUT, or COMP\_OUTDEF. After initializing the power meter, the controller requests the Signal Generator's RF frequency with the command CC\_FREQ? and waits for a response. When a response is received, it gets a power meter reading and sends it to the Signal Generator with the command CC\_RDPOWER. It remains in the main loop until the Signal Generator returns the end code "9E+09, HZ" in response to the CC\_FREQ? command. The main loop is then exited and the data is saved with the CC\_SAVE command.

```

initiate the Output Compensation Procedure with "COMP_OUT"
      or the Output with Default Attenuator Procedure with "COMP_OUTDEF"
initialize power meter
zero power meter

MAIN_LOOP:
  request the RF frequency with "CC_FREQ?"

  if( frequency = 9e9) goto DONE

  request the target level with "CC_TARGET?"
  read power meter
  send reading to 6082A with "CC_RDPOWER"

  goto MAIN_LOOP

DONE:
store new data in compensation memory with "CC_SAVE"
end

```

Figure 7-2. Basic Structure of an Output Compensation Program

The controller queries the Signal Generator's RF frequency at each step to synchronize its actions with the Signal Generator and to determine when the procedure is complete. When the Signal Generator receives a reading, it updates its internal settings and does not respond to the next frequency query until it is ready for another reading. This forces the controller to wait for the Signal Generator's output to settle before it is allowed to take another reading.

When the controller receives two consecutive readings within 0.01 dB of the target level, it considers the displayed adjustment value correct and cycles to the next step.

The controller program must ensure that each power meter reading is settled before sending it to the 6082A. In addition, the frequency dependent power meter calibration factor must be applied to every reading. The program listing in Appendix G uses a simple but effective method to obtain valid power meter readings.

The Signal Generator must be operated at room temperature for at least one hour with the module plate covers in place before performing this compensation procedure.

Proceed as follows to execute the Remote Output Compensation Procedure:

1. Press   , then program 350 MHz and +9 dBm.
2. Zero the power meter and select the power meter calibration factor.
3. Connect the power meter sensor to the Signal Generator's RF output.
4. Measure the RF level. If it is more than +9.0 dBm  $\pm$  1.0 dB, the A31 Output PCA or A35 Attenuator/RPP Assembly is not operating correctly. Refer to Section 6 in this manual for troubleshooting and repair information.
5. Set the rear panel CAL|COMP switch to the 1 (on) position. Verify that the CAL and COMP annunciators on the front panel are flashing.

### CAUTION

Do not turn the power off while the CAL|COMP switch is set on. The CAL|COMP switch protects the compensation memory from accidental damage.

6. Run the controller program.
7. Zero the RF Level Closed-Case Calibration Factor to provide maximum adjustment range. This step may be performed at the beginning of the procedure between steps 5 and 6 if desired. However, doing so may introduce a fixed offset which must be compensated for at every measurement step. To zero the RF Level Calibration Factor:
  - a. Enter
  - b. Use the edit knob to adjust the calibration factor until it reads 0.00 dB.
  - c. Press  twice to store the new calibration factor.
8. Set the rear panel CAL|COMP switch to the 0 (off) position. Verify that the CAL and COMP annunciators on the front panel are not flashing.
9. Remove the bottom instrument cover and the RF level adjustment access screw labeled A33R20 from the bottom module plate cover.
10. Press   , then program 350 MHz and +9 dBm.
11. Disable the RF output, zero the power meter, then enable the RF output. Select the power meter calibration factor.
12. Adjust RF level adjustment at A33R20 for a reading of exactly +9 dBm on the power meter.
13. Replace the RF level adjustment access screw and the bottom instrument cover.

### Remote Attenuator Compensation Procedure

7-14.

The structure of an attenuator flatness compensation program is outlined in Figure 7-3. Complete listings of a program that runs on a Fluke 1722A controller is in Appendix G.

The attenuator compensation procedure is initiated with the command COMP\_ATT. After initializing the measuring receiver, the controller requests the Signal Generator's RF frequency with the command CC\_FREQ? and waits for a response. When a response is received, it tunes the measuring receiver to the selected frequency, gets a power meter reading and sends it to the Signal Generator with the command CC\_RDPOWER. It continues to make measurements in the power meter mode until the first 24-dB attenuator is measured. At or below this level, all readings are made in the tuned RF mode.

```

initiate the Attenuator Compensation Procedure with "COMP_ATT"

initialize measuring receiver
initialize Local Oscillator

MAIN_LOOP:
  request the RF frequency with "CC_FREQ?"
  if( frequency = 9e9) goto DONE

  if (frequency < 1.3e9)
    tune measuring receiver to RF frequency

  if (frequency > 1.3e9)
    calculate offset frequency
    program LO to offset frequency
    enable frequency offset mode on measuring receiver
    program offset frequency on measuring receiver
    program RF frequency on measuring receiver
  endif

  recalibrate measuring receiver if needed

  request the target level with "CC_TARGET?"

  if target level > -14 dBm or frequency < 2.5 MHz
    read measuring receiver in power meter mode
    send reading to 6082A with "CC_RDPOWER"
  endif

  if target level <= -14 dBm and frequency >= 2.5 MHz
    read measuring receiver in tuned RF mode
    send reading to 6082A with "CC_RDPOWER"
  endif

  goto MAIN_LOOP

DONE:
store new data in compensation memory with "CC_SAVE"
end

```

Figure 7-3. Basic Structure of an Attenuator Level Compensation Program

To do this, the controller must query the target level at each step and switch to the tuned RF mode when it detects the transition from the 12-dB attenuator (target level -2 dBm) to the first of the five 24-dB attenuators (target level -14 dBm). The controller must recalibrate the measuring receiver at this transition, and as necessary at lower levels. The sample program performs all calibration transfers before making measurements at the given frequency to avoid conflicts between the target levels and the calibration levels.

The controller proceeds through each of the frequency steps until the controller detects that the 6082A frequency is at or above 1300 MHz. For this and all frequencies greater than 1300 MHz, it must perform the additional steps of calculating an offset frequency, enabling the frequency offset mode of the measuring receiver, programming the offset frequency, and programming the local oscillator to the 6082A frequency minus the offset frequency.

## COMPENSATION PROCEDURES

The controller continues with each frequency step until the signal generator returns the end code "9E+09, HZ" in response to the CC\_FREQ? command. The main loop is then exited and the data is saved with the CC\_SAVE command.

The controller queries the Signal Generator's RF frequency at each step to synchronize its actions with the Signal Generator and to determine when the procedure is complete. When the Signal Generator receives a reading, it updates its internal settings and does not respond to the next frequency query until it is ready for another reading. This forces the controller to wait for the Signal Generator's output to settle before it is allowed to take another reading.

When it receives two consecutive readings within 0.01 dB of the target level, it considers the displayed adjustment value correct and cycles to the next step.

The Signal Generator must be operated at room temperature for at least one hour with the module plate covers in place before performing this compensation procedure.

Proceed as follows to execute the Remote Attenuator Flatness Compensation Procedure:

1. Press **SPL** **0** **1**, then program 1 MHz, +10.0 dBm, and **SPL** **9** **2** **2**. Note that the STATUS annunciator is lit. Press **STATUS**, status code 201 (Level Correction Disabled) should be displayed.
2. Turn off the Signal Generator's RF output. Connect the the power sensor to the RF output.
3. Tune the measuring receiver to 1 MHz, select power meter mode, and zero the measuring receiver. Turn the RF output on.
4. Measure the RF level. If it is more than +10.0 dBm  $\pm 0.5$  dB, the A31 Output PCA or A35 Attenuator/RPP Assembly is not operating correctly. Refer to Section 6 in this manual for troubleshooting and repair information.
5. Disconnect the sensor lead from the RF input to the measuring receiver, and reconnect it to the RF input of the microwave converter. Connect the IF Output from the microwave converter to the RF input of the measuring receiver. See Figure 7-1 for details.
6. Program the Local Oscillator to 1300 MHz and 1 dBm. Connect the Local Oscillator RF Output to the Microwave Converter LO input.

### CAUTION

**Do not program the LO level above 1.0 dBm. Damage to the measuring receiver or microwave converter may result if higher levels are programmed.**

7. Set the rear panel CAL|COMP switch to the 1 (on) position. Verify that the CAL and COMP annunciators on the front panel are flashing.

**CAUTION**

Do not turn the power off while the CAL|COMP switch is set on. The CAL|COMP switch protects the compensation memory from accidental damage.

8. Run the controller program.
9. Zero the RF Level Closed-Case Calibration Factor to provide maximum adjustment range. This step may be performed at the beginning of the procedure between steps 5 and 6 if desired. However, doing so may introduce a fixed offset which must be compensated for at every measurement step. To zero the RF Level Calibration Factor:
  - a. Enter
  - b. Use the edit knob to adjust the calibration factor until it reads 0.00 dB.
  - c. Press  twice to store the new calibration factor.
10. Set the rear panel CAL|COMP switch to the 0 (off) position. Verify that the CAL and COMP annunciators on the front panel are not flashing.
11. Remove the bottom instrument cover and the RF level adjustment access screw labeled A33R20 from the bottom module plate cover.
12. Program   , 350 MHz and +9.0 dBm
13. Disable the RF output, zero the power meter, then enable the RF output. Select the power meter calibration factor.
14. Adjust RF level adjustment, R20 on the A33 Modulation Control PCA, for a reading of exactly +9 dBm on the power meter.
15. Replace the RF level adjustment access screw, and the instrument bottom cover.

#### 7-15. Remote Attenuator Compensation Procedure Using Power Meter

The basic structure of the attenuator compensation program using a power meter is shown in the program outline in Figure 7-4. A complete listing of a program that runs on a Fluke 1722A controller is in Appendix G.

**NOTE**

*Use of this procedure does not guarantee compliance with the 6082A level accuracy specification over temperature. For the best obtainable results, use the Remote Attenuator Compensation Procedure earlier in this section. The following procedure gives good results with much less test equipment and in less time.*

The programming commands used in a remote level flatness compensation procedures are listed in Table 7-5. Refer to Section 5B in the 6080A/82A Operator Manual for complete syntax descriptions of each command.

## COMPENSATION PROCEDURES

```

initiate the Attenuator Compensation Procedure with Power Meter
    with "COMP_ATTPMTR"
initialize power meter
zero power meter

MAIN_LOOP:
    request the RF frequency with "CC_FREQ?"

    if( frequency = 9e9) goto DONE

    request the target level with "CC_TARGET?"
    if( measuring 1st 24-dB pad )
        zero power meter

    read power meter
    send reading to 6082A with "CC_RDPOWER"

    goto MAIN_LOOP

DONE:
store new data in compensation memory with "CC_SAVE"
end

```

Figure 7-4. Basic Structure of an Attenuator Level Compensation Program Using Power Meter

Table 7-5. Remote Programming Commands for Level Compensation Procedure

COMMANDS	DESCRIPTION
COMP_ATT	Initiates remote attenuator compensation procedure (Using measuring receiver).
COMP_ATTPMTR	Initiates remote attenuator compensation procedure (Using power meter).
COMP_OUT	Initiates remote output compensation procedure.
COMP_OUTDEF	Initiates remote output with default attenuator data.
CC_RDPOWER	Accepts the measured power meter reading and updates its internal settings based on the reading.
CC_TARGET?	Retrieves the target RF level.
CC_FREQ?	Retrieves the current RF output frequency in Hz.
CC_SAVE	Calculates correction factors and save in compensation memory.
CC_EXIT	Exits compensation procedure immediately, discard measured data.
ERROR?	Retrieves earliest value from the error queue.
RFOUT	Enables/disables the Signal Generator RF output.

The attenuator compensation procedure using power meter is initiated with the command `COMP_ATTPMTR`. After initializing the power meter, the controller requests the Signal Generator's RF frequency with the command `CC_FREQ?` and waits for a response. When a response is received, it gets a power meter reading and sends it to the Signal Generator with the command `CC_RDPOWER`. It remains in the main loop until the Signal Generator returns the end code "9E+09, HZ" in response to the `CC_FREQ?` command. The main loop is then exited and the data is saved with the `CC_SAVE` command.

The controller queries the Signal Generator's RF frequency at each step to synchronize its actions with the Signal Generator and to determine when the procedure is complete. When the Signal Generator receives a reading, it updates its internal settings and does not respond to the next frequency query until it is ready for another reading. This forces the controller to wait for the Signal Generator's output to settle before it is allowed to take another reading.

When it receives two consecutive readings within 0.01 dB of the target level, it considers the displayed adjustment value correct and cycles to the next step.

The power meter must be zeroed before the first 24-dB attenuator is measured at each frequency. To do this, the controller must query the target level at each step and zero the power meter when it detects the transition from the 12-dB attenuator (target level -2 dBm) to the first of the five 24-dB attenuators (target level -14 dBm).

The controller program must ensure that each power meter reading is settled before sending it to the 6082A. In addition, the frequency dependent power meter calibration factor must be applied to every reading. The program listing in Appendix G uses a simple but effective method to obtain valid power meter readings.

The Signal Generator must be operated at room temperature for at least one hour with the module plate covers in place before performing this compensation procedure.

Proceed as follows to execute the Remote Attenuator Compensation Procedure Using Power Meter:

1. Press `[SPC] [0] [1]`, then program 1 MHz, +10.0 dBm, and `[SPC] [9] [2] [2]`.
2. Disable the Signal Generator's RF output and connect the the power sensor to the RF output.
3. Zero the power meter and select the power meter calibration factor. Enable the RF output.
4. Measure the RF level. If it is more than +10.0 dBm  $\pm 0.5$  dB, the A31 Output PCA or A35 Attenuator/RPP Assembly is not operating correctly. Refer to Section 6 in this manual for troubleshooting and repair information.
5. Set the rear panel CAL|COMP switch to the 1 (on) position. Verify that the CAL and COMP annunciators on the front panel are flashing.

### CAUTION

Do not turn the power off while the CAL|COMP switch is set on. The CAL|COMP switch protects the compensation memory from accidental damage.

6. Run the controller program
7. Zero the RF Level Closed-Case Calibration Factor to provide maximum adjustment range. This step may be performed at the beginning of the procedure between steps 5 and 6 if desired. However, doing so may introduce a fixed offset which must be compensated for at every measurement step. To zero the RF Level Calibration Factor:
  - a. Enter
  - b. Use the edit knob to adjust the calibration factor until it reads 0.00 dB.
  - c. Press  twice to store the new calibration factor.
8. Set the rear panel CAL|COMP switch to the 0 (off) position. Verify that the CAL and COMP annunciators on the front panel are not flashing.
9. Remove the bottom instrument cover and the RF level adjustment access screw labeled A33R20 from the bottom module plate cover.
10. Program   , 350 MHz and +9.0 dBm
11. Disable the RF output, zero the power meter, then enable the RF output. Select the power meter calibration factor.
12. Adjust RF level adjustment, R20 on the A33 Modulation Control PCA, for a reading of exactly +9 dBm on the power meter.
13. Replace the RF level adjustment access screw, and the instrument bottom cover.

### SUB-SYNTHESIZER COMPENSATION PROCEDURES

7-16.

The Sunsynthesizer Compensation Procedures generate the instrument-specific Sunsynthesizer VCO compensation data. The procedures must be performed following any repair to the A3 Sunsynthesizer VCO PCA that affects the software compensation data.

The procedure involves measuring the slope of the Sunsynthesizer VCO tuning voltage at selected frequencies. The measurement is performed by adjusting the RF frequency until the voltage change measured with an external voltmeter matches the target voltage change. The slope can then be calculated from the known frequency adjustment and voltage change. The compensation DAC values are calculated from the measured slopes and stored in the compensation memory.

**Front Panel Sunsynthesizer Compensation Procedure**

7-17.

- Number of Measurement Steps: 18
- Target Voltage Change: 0.100V
- External Equipment: 4 ½-Digit Voltmeter (Fluke 8840A or equivalent DVM with a display offset mode).

The Front Panel Sunsynthesizer Compensation Procedure is initiated by the following key sequence:

The target voltage difference of 0.100V is displayed in the MODULATION field. The RF frequency/adjustment is displayed in the FREQUENCY field. The Sunsynthesizer VCO identifier code A3 is displayed in the AMPLITUDE field and the COMP and VCO annunciators are lit to signify that the procedure is in progress.

When performing the procedure, connect the voltmeter to TP27 on the A4 Sunsynthesizer PCA. Use the edit knob to adjust the RF frequency until the measured change in voltage at TP27 matches the target voltage change. The sequence is repeated for all 18 frequencies. This procedure typically takes 15 minutes to perform.

Table 7-6 summarizes the operation of the front panel keys used during the Front Panel Sunsynthesizer Compensation Procedure. All other keys are ignored.

The Signal Generator must be operated at room temperature for at least one hour with the module plate covers in place before performing this compensation procedure. Proceed as follows to execute the Front Panel Sunsynthesizer Compensation Procedure:

1. Set the rear panel CAL|COMP switch to the 1 (on) position. Verify that the CAL and COMP annunciators on the front panel are flashing.

**CAUTION**

**Do not turn the power off while the CAL|COMP switch is set on. The CAL|COMP switch protects the compensation memory from accidental damage.**

2. Remove the instrument top cover.
3. Remove the plug button from the access hole labeled A4TP27 on the top side of the upper module plate. Connect the positive voltmeter probe to TP27 and the negative to ground.
4. Select the DC Volts mode of the Voltmeter with autoranging enabled.
5. Press     to initiate the Sunsynthesizer compensation procedure. Verify that COMP and VCO annunciators are lit.
6. Zero the voltmeter display by enabling the offset mode.

## COMPENSATION PROCEDURES

Table 7-6. Front Panel Controls for Subsynthesizer Compensation Procedure

CONTROLS	FUNCTION AND DESCRIPTION
 	BRIGHT DIGIT EDITING
KNOB	Turn edit knob to increment or decrement the frequency adjustment. Use left/right arrow keys to move the bright digit within the adjustment field.
	RF ON/OFF Toggles the RF output on/off.
	OVERRANGE/UNCAL or REJECTED ENTRY STATUS Normally displays the overrange/uncal status. Displays the rejected entry status code if there is a rejected entry.
	APPLY ESTIMATED FREQUENCY ADJUSTMENT Programs a calculated frequency adjustment that will closely approximate the final adjustment for the current step.
	STORE MEASURED DATA Press key once, the prompt "Sto ?" is displayed. Press key again to store the data. "-- Sto --" is displayed for about 5 seconds until the store operation is complete. Attempts to store the data before all steps have been measured will be rejected with error code 92. Press any other key to cancel the store operation and resume the procedure.
<b>CAUTION</b> Do not turn the power off or change the CAL COMP switch until the store operation is complete. Doing so could damage the contents of the compensation memory.	
	ABORT THE PROCEDURE Press the key once, the prompt "Clr ?" is displayed. Press the key again to abort the procedure. "-- Clr --" is displayed to confirm the selection. All measured data is discarded and the previous instrument state is restored. Press any other key to resume the procedure.

7. Press  to program an estimated frequency adjustment.
8. Adjust the RF frequency using the edit knob until the voltmeter displays a 0.100 V offset.
9. Press STEP  to go to the next step.
10. Repeat steps 6 through 9 until the last measurement step has been completed at 320 MHz.
11. Press the  key twice to store the data.

### NOTE

*If the store operation is rejected (flashing "--Sto--"), press  to determine the cause of the rejected entry. Refer to the list of rejected entry error codes in Appendix C.*

12. Set the rear panel CAL|COMP switch to the 0 (off) position. Verify that the CAL and COMP annunciators on the front panel are not flashing.
13. Install the plug button for the TP27 access hole, and install the instrument top cover.

### Remote Sunsynthesizer Compensation Procedure

7-18.

The following paragraphs describe the remote Sunsynthesizer Compensation Procedure. It describes the remote commands used in the procedure and the elements required to build a functioning controller program.

The basic structure of the Sunsynthesizer Compensation Program is shown in Figure 7-5. A complete listing of a program that runs on a Fluke 1722A controller is in Appendix G.

```

initiate the Sunsynthesizer Compensation Procedure with COMP_SUBSYN
initialize voltmeter

MAIN_LOOP:
  request the RF frequency with CC_FREQ?

  if( frequency = 9e9) goto DONE

  read voltmeter
  send reading to 6082A with CC_RDDVM
  goto MAIN_LOOP

DONE:
  store new data in compensation memory with CC_SAVE
end

```

Figure 7-5. Basic Structure of Sunsynthesizer Compensation Program

The procedure is initiated by the command COMP\_SUBSYN. The controller requests the Signal Generator's RF frequency with the command CC\_FREQ? and waits for a response. When a response is received, it obtains a voltmeter reading and sends it to the 6082A with the command CC\_RDDVM. It remains in the main loop until the 6082A returns the end code "9E+09,HZ" in response to the CC\_FREQ? command. The main loop is then exited and the data is saved with the CC\_SAVE command.

Each time the 6082A receives a reading from the controller, it adjusts its internal settings and programs the new RF frequency. When it receives two consecutive readings within 0.001V of the target voltage change (0.100V) it considers the displayed adjustment value correct and cycles to the next step.

The controller program must ensure that each voltmeter reading is settled before sending it to the 6082A. The program listing in Appendix G uses a simple but effective method to obtain valid voltmeter readings.

NOTE

*The rear panel CAL|COMP switch must be set to the 1 (on) position before initiating the compensation procedure.*

The programming commands used in a remote Sunsynthesizer Compensation Procedure are listed in Table 7-7. See the Operator Manual for complete syntax descriptions of each command.

Table 7-7. Remote Programming Commands for Subsynthesizer Comp Procedure

COMMANDS	DESCRIPTION
COMP_SUBSYN	Initiates the remote Subsynthesizer compensation procedure
CC_RDDVM	Sends the voltmeter reading to the 6080A
CC_FREQ?	Requests the current RF frequency
CC_TARGET?	Requests the target value
CC_SAVE	Saves the measured data
CC_EXIT	Aborts the compensation procedure immediately
ERROR?	Requests the rejected entry status

**COARSE LOOP COMPENSATION PROCEDURES**

7-19.

The coarse loop compensation procedures generate the instrument-specific compensation data for the A5 Coarse Loop VCO PCA. The procedures must be performed following a module replacement or repair that affects the coarse loop VCO compensation data.

The procedures can be initiated from the front panel or remotely through the IEEE-488 interface. Once initiated, they require no user interaction and need no external measurement equipment. Upon successful completion, the new data is automatically stored in the compensation memory on the A13 Controller PCA. The procedures can be performed in approximately 5 minutes.

The coarse frequency synthesis loop is programmable from 576 MHz to 960 MHz in 8-MHz steps. There is a unique steering DAC and compensation DAC value for each of the 49 steps. The coarse loop compensation procedure generates the steering DAC and compensation DAC values for the entire frequency range.

**Front Panel Coarse Loop Compensation Procedure**

7-20.

Refer to Table 7-8 for a description of front panel controls used in for coarse loop compensation procedures. The front panel coarse loop compensation procedure is initiated by the following key sequence:    .

The COMP and VCO annunciators are lit and the coarse loop VCO PCA identifier A5 is displayed in the frequency field to signify that the coarse loop compensation procedure is in progress. Table 7-8 shows all of the active controls and describes their function while performing the procedure.

Table 7-8. Front Panel Controls for Coarse Loop Compensation Procedure

CONTROLS	FUNCTION AND DESCRIPTION
<div style="border: 1px solid black; padding: 2px; width: fit-content; margin: 5px auto;">CLR LCL</div>	<p>Pause/Abort the procedure</p> <p>Press once; the procedure is paused and the prompt "Clr ?" is displayed.</p> <p>Press again to abort the procedure. "-- Clr --" is displayed to confirm the selection. All measured data is discarded, and the previous instrument state is restored.</p> <p>Press any other key to resume the procedure.</p>

A 30 second countdown timer is displayed while the coarse loop VCO circuitry thermally stabilizes. This warmup delay is also inserted at the beginning of the second and third VCO bands.

Next, the initial coarse loop frequency of 576 MHz is programmed and is displayed. The software determines the optimal DAC values for the frequency using an iterative search algorithm. The process is repeated every 8 MHz until the entire frequency range has been measured. Upon completion, the message "-- Sto --" is displayed and the measured data is loaded into the compensation memory.

If the correct DAC value for any step cannot be found, the procedure is exited immediately and the coarse loop frequency where the problem was encountered is flashed in the FREQUENCY display field.

The Signal Generator must be operated at room temperature for at least one hour with the module plate covers in place before performing this compensation procedure. Proceed as follows to execute the front panel coarse loop compensation procedure:

1. Set the rear panel CAL|COMP switch to the 1 (on) position.

**CAUTION**

**Do not turn the power off or change the CAL|COMP switch until the store operation is complete. Doing so could damage the contents of the compensation memory.**

2. Enter SPL 9 7 1 to initiate the procedure.
3. Wait for the procedure to complete.
4. Set the rear panel CAL|COMP switch to the 0 (off) position.

**Remote Coarse Loop Compensation Procedure**

**7-21.**

The remote coarse loop compensation procedure is identical to the front panel procedure with the exception that it is initiated by the remote command COMP\_COARSE rather than by Special Function.

The program listing in Figure G-7 in Appendix G illustrates how to initiate the procedure and how to use the \*OPC? command to make the controller wait until the procedure is complete.

## COMPENSATION PROCEDURES

If the correct DAC value for any step cannot be found, the procedure is exited immediately and the coarse loop frequency where the problem was encountered is flashed in the FREQUENCY display field. The error code and frequency can also be interrogated through the remote interface at a later time with the command CC\_ERRFREQ?. The error frequency information is retained until the instrument is powered down.

The commands used in the remote coarse loop compensation procedure are listed in Table 7-9. See Section 5B in the Operator Manual for complete syntax descriptions of each command.

Table 7-9. Remote Programming Commands for Coarse Loop Compensation Procedure

COMMANDS	FUNCTION AND DESCRIPTION
COMP_COARSE	Initiates the remote coarse loop compensation procedure.
CC_EXIT	Exits the compensation procedure immediately.
CC_ERRFREQ?	Reports the most recent coarse loop or sum loop compensation procedure error code and the frequency where the error occurred.
ERROR?	Requests the rejected entry status.

## SUM LOOP COMPENSATION PROCEDURES

7-22.

The sum loop compensation procedures generate the instrument-specific compensation data for the A9 Sum Loop VCO PCA. The procedures must be performed following a module replacement or repair that affects the sum loop VCO compensation data.

The procedures can be initiated from the front panel or remotely through the IEEE-488 interface. Once initiated, they require no user interaction and need no external measurement equipment. Upon successful completion, the new data is automatically stored in the compensation memory on the A13 Controller PCA. The procedures can be performed in approximately 5 minutes.

The sum loop frequency range is from 480 MHz to 1056 MHz. There is a unique steering DAC and compensation DAC value every 1 MHz. The sum loop compensation procedure generates the steering DAC and compensation DAC values for the entire frequency range.

### Front Panel Sum Loop Compensation Procedure

7-22.

The front panel sum loop compensation procedure is initiated by the following key sequence: **SPCL** **9** **7** **2**

The COMP and VCO annunciators are lit and the sum loop VCO PCA identifier A9 is displayed in the amplitude field to signify that the Sum Loop Compensation Procedure is in progress. Table 7-10 shows all of the active controls and describes their function while performing the procedure.

A 30 second countdown timer is displayed while the sum loop VCO circuitry thermally stabilizes. This warmup delay is also inserted at the beginning of the other three VCO bands.

Table 7-10. Front Panel Controls for Sum Loop Compensation Procedure

CONTROLS	FUNCTION AND DESCRIPTION
<div style="border: 1px solid black; padding: 2px; display: inline-block;">CLR LCL</div>	Pause/Abort the procedure Press once; the procedure is paused and the prompt "Clr ?" is displayed. Press again to abort the procedure. "-- Clr --" is displayed to confirm the selection. All measured data is discarded, and the previous instrument state is restored. Press any other key to resume the procedure.

Next, the initial sum loop frequency of 480 MHz is programmed and is displayed. The software determines the optimal DAC values for the frequency using an iterative search algorithm. The process is repeated every 5 MHz until the entire frequency range has been measured. Upon completion, the measured DAC values are interpolated to 1 MHz steps, the message "-- Sto --" is displayed and the measured data is loaded into the compensation memory.

If the correct DAC value for any step cannot be found, the procedure is exited immediately and the sum loop frequency where the problem was encountered is flashed in the FREQUENCY display field.

The Signal Generator must be operated at room temperature for at least one hour with the module plate covers in place before performing this compensation procedure.

Proceed as follows to execute the front panel sum loop compensation procedure:

1. Set the rear panel CAL|COMP switch to the 1 (on) position.

#### CAUTION

**Do not turn the power off or change the CAL|COMP switch until the store operation is complete. Doing so could damage the contents of the compensation memory.**

2. Enter SPL 9 7 2 to initiate the procedure.
3. Wait for the procedure to complete.
4. Set the rear panel CAL|COMP switch to the 0 (off) position.

### Remote Sum Loop Compensation Procedure

7-24.

The Remote Sum Loop Compensation Procedure is identical to the front panel procedure except that it is initiated by the remote command COMP\_SUM rather than by Special Function. A program listing in Appendix G illustrates how to initiate the procedure and how to use the \*OPC? command to make the controller wait until the procedure is complete.

If the correct DAC value for any step cannot be found, the procedure is exited immediately and the sum loop frequency where the problem was encountered is flashed in the FREQUENCY display field. The error code and frequency can also be interrogated through the remote interface at a later time with the command CC\_ERRFREQ?. The error frequency information is retained until the instrument is powered down.

## COMPENSATION PROCEDURES

The commands used in the remote sum loop compensation procedure are listed in Table 7-11. Refer to Section 5B in the 6080A/82A Operator Manual for complete syntax descriptions of each command.

**Table 7-11. Remote Programming Commands for Sum Loop Compensation Procedure**

COMMANDS	FUNCTION AND DESCRIPTION
COMP_SUM	Initiates the remote sum loop compensation procedure.
CC_EXIT	Exits the compensation procedure immediately.
CC_ERRFREQ?	Reports the most recent sum loop or coarse loop compensation procedure error code and the frequency where the error occurred.
ERROR?	Requests the rejected entry status.

## INTRODUCTION

8-1.

Section 8 contains an illustrated list of replaceable parts for the 6082A Synthesized RF Signal Generator. Parts are listed by assembly, alphabetized by reference designator. Each assembly is accompanied by an illustration showing the location of each part and its reference designator. The parts lists include the following information:

- The reference designator of the part.
- An indication if the part is subject to damage by static discharge.
- A description of the part.
- The stock number of the part.
- The manufacturer's supply code (that is, the CAGE code) of the maker of the part (a code-to-name list is provided at the end of this section).
- The manufacturer's part number or generic type of the part.
- The total quantity of components per assembly.
- Any special notes (i.e., factory-selected part).

### CAUTION

*Parts labeled with an asterisk (\*) in the 'S' column are subject to damage by static discharge.*

## HOW TO OBTAIN PARTS

8-2.

Electrical components may be ordered directly from the manufacturer by using the manufacturer's part number, or from Giga-tronics Inc. (or its authorized representative ) by using the stock number shown in the parts list. A list of federal supply codes is provided at the end of this section.

To ensure prompt and efficient handling of your order, include the following information:

- Stock number (six-digit part number).
- Description.
- Reference designator (e.g., R112).
- Quantity.
- Part Number and revision level of the assembly containing the part.
- Price information is available from Giga-tronics Inc. or its representative.

## **LIST OF REPLACEABLE PARTS**

### **MANUAL STATUS INFORMATION**

**8-3.**

The first table in this section lists the revision levels for the printed circuit assemblies that are documented in this manual. Revision levels are printed on the component side of each PCA.

### **SERVICE CENTERS**

**8-4.**

A list of technical service centers is provided at the end of this section.

## Section 9 Options

### INTRODUCTION

9-1.

This section includes operation notes, a description, and maintenance instructions for each option. Each of these options must be installed at the factory or at one of the Fluke Technical Service Centers listed in Section 8. Each of these options is used interchangeably for Model 6080A or 6082A.

### 6080A-130 HIGH-STABILITY REFERENCE

9-2.

With the rear panel REF INT/EXT switch set to INT, the 6080A-130 Option takes over the 10-MHz internal reference function. Stability specifications are enhanced as defined in the Specifications in Section 1.

The High-Stability Reference consists of an ovened oscillator (Y1), mounting hardware, and cables. The ovened oscillator is not field repairable.

#### NOTE

*The oscillator oven stays energized whenever line power is connected to an ac outlet. The oven stays warmed to the correct temperature regardless of the POWER switch or internal/external reference setting.*

### Adjusting the Reference Frequency

9-3.

#### CAUTION

**THIS ADJUSTMENT REQUIRES OPERATING THE INSTRUMENT WITH THE TOP COVER REMOVED. USE CARE TO AVOID ELECTRIC SHOCK. ONLY QUALIFIED PERSONNEL SHOULD PERFORM THIS PROCEDURE.**

You can adjust the frequency of the High-Stability Reference. The following test equipment is required:

- 10 MHz frequency standard
- Dual-trace oscilloscope
- Two 3-ft 50 $\Omega$  coaxial cables and 50 $\Omega$  BNC feedthrough terminations

#### NOTE

*Operate the Signal Generator at room temperature for at least three hours before adjusting the High-Stability Reference frequency.*

Proceed as follows to adjust the High-Stability Reference frequency:

1. Remove the top instrument cover and the two FREQ ADJ access screws from the side of the ovened oscillator facing the front panel.
2. Connect the frequency standard to the oscilloscope vertical input channel 1 using a 50 $\Omega$  feedthrough termination at the oscilloscope input.
3. Connect the Signal Generator rear panel 10 MHz OUT BNC connector to the oscilloscope vertical input channel 2 using a 50 $\Omega$  feedthrough termination at the oscilloscope input.
4. Set the Signal Generator rear panel REF INT/EXT switch to INT.
5. Set the vertical controls of the oscilloscope to display the Signal Generator's 10-MHz internal reference signal and the signal from the frequency standard.
6. Set the oscilloscope for internal triggering on channel 1, and adjust the timebase for 0.1  $\mu$ s/div.
7. Adjust the High-Stability Reference COARSE control for the best match of the frequencies displayed on the oscilloscope.
8. Adjust the High-Stability Reference FINE control for a drift of less than one cycle in 10 seconds (for 0.01 ppm) or better if desired.

### List of Replaceable Parts

9-4.

A list of replaceable parts for the 6080A-130 Option is provided in Table 9-1. Figure 9-1 shows the location of the ovened oscillator and its associated parts.

### 6080A-132 MEDIUM-STABILITY REFERENCE

9-5.

With the rear panel REF INT/EXT switch set to INT, the 6080A-130 Option takes over the 10-MHz internal reference function. Stability specifications are enhanced as defined in the Specifications in Section 1.

The Medium-Stability Reference consists of an ovened oscillator (Y1), mounting hardware, and cables. The ovened oscillator is not field repairable.

#### NOTE

*The oscillator oven stays energized whenever line power is connected to an ac outlet. The oven stays warmed to the correct temperature regardless of the POWER switch or internal/external reference setting.*

### Adjusting the Reference Frequency

9-6.

#### CAUTION

**THIS ADJUSTMENT REQUIRES OPERATING THE INSTRUMENT WITH THE TOP COVER REMOVED. USE CARE TO AVOID ELECTRIC SHOCK. ONLY QUALIFIED PERSONNEL SHOULD PERFORM THIS PROCEDURE.**

You can adjust the frequency of the Medium-Stability Reference. The following test equipment is required:

- 10 MHz frequency standard
- Dual-trace oscilloscope
- Two 3-ft 50 $\Omega$  coaxial cables and 50 $\Omega$  BNC feedthrough terminations.

*NOTE*

*Operate the Signal Generator at room temperature for at least three hours before adjusting the Medium-Stability Reference frequency.*

Proceed as follows to adjust the Medium-Stability Reference frequency:

1. Remove the top instrument cover and the **FREQ ADJ COARSE** adjustment access screw from the side of the ovened oscillator facing the front panel.
2. Connect the frequency standard to the oscilloscope vertical input channel 1 using a 50 $\Omega$  feedthrough termination at the oscilloscope input.
3. Connect the Signal Generator rear panel 10 MHz OUT BNC connector to the oscilloscope vertical input channel 2 using a 50 $\Omega$  feedthrough termination at the oscilloscope input.
4. Set the Signal Generator rear panel REF INT/EXT switch to INT.
5. Set the vertical controls of the oscilloscope to display the Signal Generator's 10-MHz internal reference signal and the signal from the frequency standard.
6. Set the oscilloscope for internal triggering on channel 1, and adjust the timebase for 0.1  $\mu$ s/div.
7. Adjust the Medium-Stability Reference **FREQ ADJ COARSE** control for a drift of less than one cycle in 10 seconds (for 0.01 ppm) or better if desired.

**List of Replaceable Parts**

**9-7.**

A list of replaceable parts for the 6080A-132 Option is provided in Table 9-2. Figure 9-1 shows the location of the ovened oscillator and its associated parts.

**OPTION 6080A-830 REAR OUTPUT/MODULATION INPUT**

**9-8.**

Option 6080A-830 moves the RF OUTPUT, MOD OUTPUT, and MODULATION INPUT connectors from the front panel to the rear panel. This option does not change the operation, specifications, performance tests, calibration, adjustment, or service of the Signal Generator.

**Theory of Operation**

**9-8.**

When the 6080A-830 Option is installed, a longer internal semi-rigid coaxial SMA cable assembly replaces the standard internal cable for the Signal Generator's RF output. The option switch on the A13 Controller PCA is set to indicate that the option is installed. The setting of the Controller PCA option switch causes the additional signal loss of this longer cable to be compensated with instrument-independent correction data stored in compensation memory.

List of Replaceable Parts

9-9.

A list of replaceable parts for the 6080A-830 Option is provided in Table 9-3. Figure 9-2 shows the internal cabling differences from the standard front panel input/output configuration.

## **Instrument Preset State**

**INSTRUMENT PRESET STATE**

**Appendix A. Instrument Preset State**

FUNCTION	SET TO STATES		
	SPCL 00	RCL 97 <sup>1</sup>	SPCL 01 <sup>2</sup> (PRESET)
<b>FREQUENCY</b>			
Output frequency		1000 MHz	1000 MHz
Relative frequency mode (SPCL 20)	Off	Off	Off
<b>AMPLITUDE</b>			
Output amplitude		-140 dBm	-140 dBm
RF output state			On
Relative amplitude mode (SPCL 30)	Off	Off	Off
Fixed range amplitude (SPCL 50)	Normal	Normal	Normal
Amplitude display units (SPCL 840)	dBm	dBm	dBm
EMF-Volts amplitude display mode (SPCL 850)	Off	Off	Off
<b>MODULATION</b>			
AM depth		30 %	30 %
FM/ØM deviation		5 kHz	5 kHz
Modulation frequency		1 kHz	1 kHz
Modulation level		0 V	0 V
Pulse width		500 µs	500 µs
Internal AM		Off	Off
External AC AM		Off	Off
External DC AM		Off	Off
Internal FM/ØM		Off	Off
External AC FM/ØM		Off	Off
External DC FM/ØM		Off	Off
External pulse modulation		Off	Off
Modulation Oscillator output (SPCL 40)	On	On	On
Low-rate FM (SPCL 710)	Off	Off	Off
High-rate ØM (SPCL 720)	Off	Off	Off
Low-distortion/fixe range FM (SPCL 730)	Normal	Normal	Normal
Internal pulse modulation (SPCL 740)	Off	Off	Off
Modulation oscillator waveform (SPCL 750)	Sine	Sine	Sine
<b>SWEEP</b>			
Frequency sweep width		100 MHz	100 MHz
Frequency sweep increment		1 MHz	1 MHz
Amplitude sweep width		10 dB	10 dB
Amplitude sweep increment		.1 dB	.1 dB
Active sweep field		Freq.	Freq.
Sweep dwell time (SPCL 890)	0 s	0 s	0 s
Sweep symmetry (SPCL 880)	Sym.	Sym.	Sym.
Sweep mode			Off
<b>EDIT</b>			
Frequency bright-digit		10 MHz	10 MHz
Amplitude bright-digit		10 dBm	10 dBm
AM bright-digit		10 %	10 %
FM bright-digit		1 kHz	1 kHz

Appendix A. Instrument Preset State (cont)

FUNCTION	SET TO STATES		
	SPCL 00	RCL 98 <sup>1</sup>	SPCL 01 <sup>2</sup> (PRESET)
Modulation frequency bright-digit		1 kHz	1 kHz
Modulation level bright-digit		100 mV	100 mV
Modulation display field		FM	FM
Active bright-digit field		Freq.	Freq.
<b>STEP</b>			
Frequency step size		10 MHz	10 MHz
Amplitude step size		10 dB	10 dB
AM depth step size		10%	10%
FM/ØM deviation step size		1 kHz	1 kHz
Modulation frequency step size		1 kHz	1 kHz
Modulation level step size		.1 V	.1 V
Active step field		Freq.	Freq.
<b>MISCELLANEOUS</b>			
Display (SPCL 770)			On
Key repeat rate (SPCL 860)			Medium
Knob and step key operation (SPCL 870)			On, Step
Calibration/compensation procedures			Off
Amplitude compensation (SPCL 920)			All
<b>REMOTE</b>			
Service request enable (SPCL 13)			0
Event status enable			0
Instrument status change enable			0
<b>NOTES:</b>			
1. Store and recall operations include these parameters.			
2. Power-on State.			
SPCL 00 and RCL 98 are not allowed while the 6080A/AN is sweeping.			
The following instrument parameters are only set from the Fluke factory or with their associated commands:			
External reference frequency (SPCL 760)		Standard	
Memory dividers (SPCL 802)		0,0,0,0	
Memory lock state (SPCL 810)		Off	
Output compensation data (SPCL 930)		Standard	
IEEE-488 address (SPCL 10)		2	
IEEE-488 addressed/listen-only/talk-only (SPCL 11)		Addressed	
IEEE-488 language (SPCL 12)		6080 Language	
Secure mode (SPCL 820)		Off	
RF Output Blanking (SPCL 780)		Off	
Low noise external reference (SPCL 950)		Off	
Nonvolatile memory erase repeat count (SPCL 828)		12

## **Special Function Table**

# SPECIAL FUNCTION TABLE

Appendix B. Special Function Table

SPECIAL FUNCTION	DESCRIPTION
00	Clear special functions
01	Restore Instrument Preset State
02	Initiate power-on self tests
03	Display self test results
04	Display cal/comp memory checksum status
05	Display cal/comp memory data origins
06	Self tests with RF and pulse
08	Display option loading status
09	Display software revision level
10	Display/Set IEEE-488 address
11	Display/Set IEEE-488 address mode
12	Display/Set IEEE-488 language
13	Display/Enter service request mask
14	Set user request SRQ
15	Clear SRQ
20	Disable relative frequency mode
21	Enable relative frequency mode
30	Disable relative amplitude mode
31	Enable relative amplitude mode
40	Enable modulation oscillator output
41	Disable modulation oscillator output
42	Enter modulation frequency with 0.1 Hz resolution
50	Disable fixed range amplitude
51	Enable fixed range amplitude
701	Enable phase adjust mode
702	Zero phase adjust indicator
710	Disable low-rate FM
711	Enable low-rate FM
720	Disable high-rate $\emptyset$ M
721	Enable high-rate $\emptyset$ M
730	Select normal range FM
731	Select low-distortion range FM
732	Select fixed range FM
740	Disable internal pulse modulation
741	Enable internal pulse modulation
750	Select sine oscillator waveform
751	Select triangle oscillator waveform
752	Select square oscillator waveform

Appendix B. Special Function Table (cont)

SPECIAL FUNCTION	DESCRIPTION
758	Select pulse waveform
759	Enter pulse width
760	Use 10 MHz external reference input frequency
761	Use alternate external reference input frequency
770	Enable display
771	Disable display
780	Disable RF output blanking
781	Enable RF output blanking
801	Reset memory locations
802	Display/Set memory sequence dividers
808	Continuous memory sequence (860-862 select rate)
810	Unlock memory store operations
811	Lock memory store operations
820	Disable secure mode
821	Enable secure mode
828	Nonvolatile memory erase repeat count
829	Erase nonvolatile memory
840	Select dBm amplitude display units
841	Select dBmV amplitude display units
842	Select dBuV amplitude display units
843	Select dBf amplitude display units
850	Disable EMF-Volts amplitude display mode
851	Enable EMF-Volts amplitude display mode
860	Select medium key repeat rate
861	Select fast key repeat rate
862	Select slow key repeat rate
870	Normal knob and step key operation
871	Knob disabled, normal step key operation
872	Normal knob, step keys operate as EDIT up/down
873	Knob disabled, step keys operate as EDIT up/down
880	Select symmetrical sweep symmetry
881	Select asymmetrical sweep symmetry
882	Initiate single sweep
890	Select sweep dwell time of 0 ms
891	Select sweep dwell time of 20 ms
892	Select sweep dwell time of 50 ms
893	Select sweep dwell time of 100 ms
894	Select sweep dwell time of 200 ms
895	Select sweep dwell time of 500 ms
896	Select sweep dwell time of 1s

# SPECIAL FUNCTION TABLE

Appendix B. Special Function Table (cont)

SPECIAL FUNCTION	DESCRIPTION
897	Select sweep dwell time of 2s
898	Select sweep dwell time of 5s
899	Select sweep dwell time of 10s
901	Display test
902	Button test
903	Latch test
904	Initiate self tests with RF output enabled
905	Display operating time since manufacture in hours
907	Repair cal/comp memory checksum errors
909	Diagnostic preset state
910	Rear output option (-830) installed
920	Enable amplitude compensation
921	Disable all amplitude compensation
922	Disable attenuator amplitude compensation
923	Program alternate A24b attenuator
924	Program alternate A24c attenuator
925	Program alternate A24d attenuator
926	Program alternate A24e attenuator
930	Use normal output compensation data
931	Use alternate output compensation data
941	Set all internal DACs to zero
942	Set all internal DACs to half scale
943	Set all internal DACs to full scale
945	Display sum loop frequency
946	Display coarse loop frequency
947	Display subsynthesizer frequency
950	Disable low noise external reference mode
951	Enable low noise external reference mode
961	Transfer output MEC prom data
962	Transfer attenuator MEC prom data
963	Transfer subsynthesizer MEC prom data
971	Automatic coarse loop compensation procedure
972	Automatic sum loop compensation procedure
981	Front panel output compensation procedure
982	Front panel output compensation w/default attenuator procedure
983	Front panel attenuator compensation procedure
984	Front panel subsynthesizer compensation procedure
988	Front panel attenuator comp procedure (power meter)
989	Display Het offset adjustment following output comp procedure
991	Front panel AM calibration procedure
992	Front panel FM calibration procedure
993	Front panel level calibration procedure
994	Front panel reference oscillator calibration procedure

339-356	Filter tests (See Service Manual)

## Appendix F

# Using Rear Panel AUX Connector Pinout

**REAR PANEL VIEW**

PIN	DIRECTION	FUNCTION
1	Input	Sequence down memory location
2	Input	Sequence up memory location
3	--	Ground
4	Output	Pen Lift/Blanking, TTL
5	Output	Sweep DAC, 0-10V
6	--	--
7	--	--
8	--	--
9	Input	Toggle bright digit between frequency and amplitude fields.

**NOTE:** This connector is for foot-pedal or other external switch control. The input lines are active when taken to ground (pin 3). The inputs lines do not repeat if held at ground. The pin 5 output, Sweep DAC, is a 0-10v dc analog signal for driving a plotter. See Section 4E in the Operator manual for more information.

## Appendix G

# Example Calibration Controller Programs

Appendix G consists of eight figures. Each figure is a listing of a calibration program that will run on the Fluke 1722A Controller. These figures are listed below:

- Figure G-1. Example AM Calibration Control Program
- Figure G-2. Example FM Calibration Control Program
- Figure G-3. Example Level Calibration Control Program
- Figure G-4. Example Reference Calibration Control Program
- Figure G-5. Example Output/Attenuator Compensation and Level Cal Program
- Figure G-6. Example Sub-Synthesizer Compensation
- Figure G-7. Example Coarse Loop Compensation
- Figure G-8. Example Sum Loop Compensation

  - Parts list, 8-73
  - Schematic, 10-61
- Removing PCAs, see access procedures and replacing modules
- Replacing modules, 6-5
  - A1 Display PCA, 6-7
  - A2 Coarse Loop PCA, 6-7
  - A3 Subsynthesizer VCO PCA, 6-7
  - A4 Subsynthesizer PCA, 6-7
  - A5 Coarse Loop VCO PCA, 6-7
  - A6 Mod Oscillator PCA, 6-7
  - A7 Relay Driver PCA, 6-7
  - A9 Sum Loop VCO PCA, 6-8
  - A12 Sum Loop PCA, 6-9
  - A13 Controller PCA, 6-9
  - A14 FM PCA, 6-9
  - A15 Power Supply PCA, 6-9
  - A19 Switch PCA, 6-9
  - A22 Delay Line Assembly (A25, A26, Delay Cable, Trim Cable), 6-9
  - A31 Output PCA, 6-8
  - A32 Premodulator PCA, 6-8
  - A33 Modulation Control PCA, 6-8
  - A35 Attenuator/RPP Assembly (A35A7, A35A34), 6-9
- Updating compensation memory with module exchange data, 6-10
- Residual AM noise test, 3-21
- RF level adjustments, 6D-10
  - FM Gain Adjustment, R82, on Mod Control PCA, 6D-21
  - FM INV Balance, R102 on Mod Control PCA, 6D-21
  - FM Steer Gain, R101 on Mod Control PCA, 6D-21
  - Mod Control PCA AM DAC Offset Adjustment, R8, 6D-13
  - Mod Control PCA AM Depth Adjustment, R10, 6D-15
  - Mod Control PCA External Modulation Level Indicator Adjustment, R71, 6D-17
  - Mod Control PCA Level DAC Offset Adjustment, R23, 6D-12
  - Mod Control PCA RF Level Adjustment, R20, 6D-16
  - Mod Control PCA Sum Steer Gain Adjustment, R99, 6D-17
  - Output PCA Het Level Adjustment, R96, 6D-18
  - Output PCA Overall Gain Adjustment, R143, 6D-19
  - Output PCA Q5 Bias Adjustment, R46, and Q6 Bias Adjustment, R73, 6D-20
- Premodulator PCA Bandwidth Adjustment, R51, 6D-18
- RF level
  - Block diagram, 6D-2
  - Calibration, 4-9
    - Front panel procedure, 4-10
    - Remote procedure, 4-10
  - Circuit description, 6D-4
    - Level control, 6D-7
    - Leveling loop, 6D-7
    - RF path, 6D-4
  - Troubleshooting, 6D-8
    - Fault tree, 6D-1
    - Output assembly test point signal information, 6D-11
    - Unleveled condition, 6D-9
- Safety, following Title Page, 5-1
- Schematic diagrams
  - A1 Display PCA, 10-3
  - A2 Coarse Loop PCA, 10-6
  - A3 Subsynthesizer VCO PCA, 10-11
  - A4 Subsynthesizer PCA, 10-13
  - A5 Coarse Loop VCO PCA, 10-17
  - A6 Mod Oscillator PCA, 10-19
  - A9 Sum Loop VCO PCA, 10-22
  - A12 Sum Loop PCA, 10-24
  - A13 Controller PCA, 10-28
  - A14 FM PCA, 10-33
  - A15 Power Supply PCA, 10-38
  - A16 IEEE Connector PCA, 10-41
  - A17 Cable Transition PCA, 10-42
  - A18 Cable Transition PCA, 10-43
  - A19 Switch PCA, 10-44
  - A22 Delay Line Assembly, 10-46
  - A31 Output PCA, 10-48
  - A32 Premodulator PCA, 10-52
  - A33 Modulation Control PCA, 10-57
  - A35A7 Relay Driver PCA, 10-61
  - A35A34 Attenuator PCA, 10-63
- Self test status codes, E-1
- Self tests, 6-11
  - AM, 6-12
  - Coarse loop, 6-13
  - DC FM, 6-13
  - Digital, 6-11
  - Filter, 6-15
  - FM, 6-12
  - $\phi$ M, 6-13
  - Pulse modulator, 6-15
  - RF output, 6-14
  - Subsynthesizer, 6-14
  - Sum loop, 6-14
- Service centers, 8-4
- Special function table, B-1
- Specifications, 1-2
- Status
  - And control latches, 6B-4
  - Signals and status codes, 6-15

- Subsynthesizer PCA (A4)
  - Access procedure, 5-5
  - Adjustments, 6C-13
    - 10-kHz notch adjustment, L56, 6C-15
    - Lower clamp adjustment, R99, 6C-13
    - SSB mixer LO drive adjustment, R106, 6C-14
    - Steering DAC full-scale adjustment, 6C-13
    - Upper clamp adjustment, R98, 6C-14
  - Block diagram, 6C-3
  - Circuit description, 6C-1
    - DACs and latches, 6C-9
    - Loop amplifier, 6C-9
    - Low-order digits generator, 6C-9
    - N-divider, 6C-4
    - Phase detector, 6C-8
    - Single-sideband mixer, 6C-1
  - Compensation procedures, 7-26
    - Front panel, 7-27
    - Remote, 7-29
  - Parts list, 8-29
  - Schematic, 10-13
  - Troubleshooting, 6C-9
- Subsynthesizer VCO PCA (A3)
  - Access procedure, 5-5
  - Circuit description, 6C-16
  - Parts list, 8-27
  - Schematic, 10-11
  - Troubleshooting, 6C-16
- Sum Loop PCA (A12)
  - Access procedure, 5-8
  - Adjustments, 6C-44
    - 10-kHz notch adjustment, L56, 6C-15
    - Lower clamp adjustment, R99, 6C-13
    - Steering DAC full-scale adjustment, 6C-13
    - SSB mixer LO drive adjustment, R106, 6C-14
    - Upper clamp adjustment, R98, 6C-14
  - Block diagram, 6C-36
  - Circuit description, 6C-37
    - Audio section, 6C-38
    - RF section, 6C-37
  - Compensation procedures, 7-32
    - Front panel, 7-32
    - Remote, 7-33
  - Parts list, 8-39
  - RF circuitry test information, 6C-43
  - RF section dc bias voltages, 6C-43
  - Schematic, 10-24
  - Test points, 6C-44
  - Troubleshooting, 6C-41
- Sum Loop VCO PCA (A9)
  - Access procedure, 5-7
  - Adjustment, 6C-50
  - Block diagram, 6C-36
  - Circuit description, 6C-48
  - Parts list, 8-37
  - Schematic, 10-22
  - Troubleshooting, 6C-49
- Switch PCA (A19)
  - Parts list, 8-55
  - Schematic, 10-44
- Synthesis test, 3-5
- Test equipment, 3-1
- Theory of operation, 2-1
- Troubleshooting, introduction, 6-2
- Voltage standing-wave ratio (VSWR) tests, 3-35
