

Baseband Fading Simulator ABFS

Saving costs through real-world fading tests

- 2 fading channels (4 with option ABFS-B2)
- 12 propagation paths (24 with option ABFS-B2)
- Universal use in research, development and production
- Simulation of present and future communication systems thanks to flexible concept
- Receiver tests at I/Q level together with a baseband source
- Ease of operation
- High reliability

The characteristics of a radio channel may strongly impair signal transmission between a transmitter and in particular a moving receiver.

Baseband Fading Simulator ABFS generates signals which simulate real receive conditions in mobile applications. Thus, the response of receivers under real-world conditions can be checked already during development and QM acceptance testing. The simulation of fading signals at baseband level reduces costs.

Advantages of fading simulation in baseband

Conventional fading simulators normally convert the signal of the radio channel to the IF, perform fading and then reconvert the signal to its RF frequency. It is however less costly to loop in the simulator prior to the first conversion to the carrier frequency, ie to simulate at baseband level (I and Q) and then convert to the correct frequency in the test system (see Fig. 2). Signals will therefore not be impaired by the effects of multiple conversion. Due to this baseband fading simulation an upgrade to new networks or standards is easy.

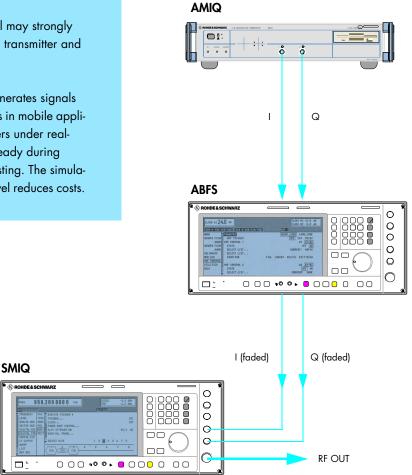

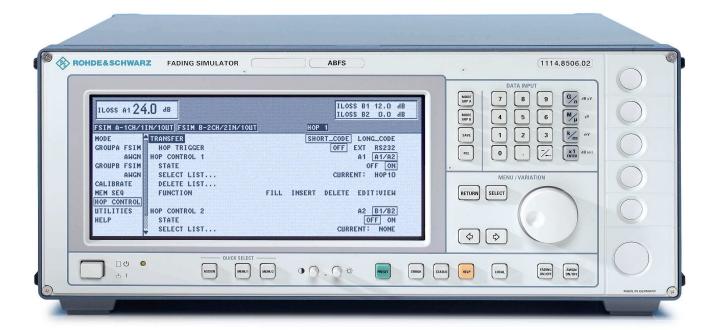

Fig. 1: Fading of a baseband signal from AMIQ with Fading Simulator ABFS

Fit for the future

Baseband Fading Simulator ABFS is suitable for universal mobile radio applications in research, development and production. It comprises all scenarios and statistical models for simulating sporadic fading as specified in the test regulations of mobile radio standards (eg GSM, IS-54/US-136 or IS-95 CDMA).

The flexible concept of ABFS allows the simulation of radio channels of existing and future communication systems (eg mobile radio, broadcasting, flight telephone, WLL, or WLAN systems).

ABFS can also simulate frequency hopping systems. ABFS is fast enough to follow the frequency hopping of a test system for example within a frame of 4,616 ms (GSM frame time).

Furthermore, an offset voltage for each I and Q input or output can be entered to compensate external DC offset voltages.

Together with a baseband source (eg I/Q Modulation Generator AMIQ from Rohde & Schwarz, see Fig. 1 on the left) receiver tests can be performed at I/Q level even if the corresponding RF link is not available. During the development of receivers or correction circuits in the receiver (eg equalizer), the effects of fading can thus be checked at a very early stage.

The basic model of ABFS comes with two independent channels for 6-path fading. The two channels can be interconnected as follows (see Fig. 3):

- Distribution of an input to two outputs (eg with different fading profiles). This feature makes it possible to simulate the signal of two antennas with different characteristics or frequency diversity methods
- Simulation of two channels with individual profiles and addition at output. Cell change or superposition of interferers can be tested with this configuration
- Coupling of two channels so that a channel with 12 propagation paths is obtained (Fig. 4 gives a more detailled insight how the fading simulator works).

High versatility by options

Noise Generator ABFS-B1 adds a noise source to the output of the first channel (see Fig. 3) so that noise can be simulated in the frequency band used. The noise generator can be switched on or off irrespective of the operating modes of the basic version.

Second Fading Simulator ABFS-B2

offers two extra channels with the same characteristics in addition to the two channels of the basic model.

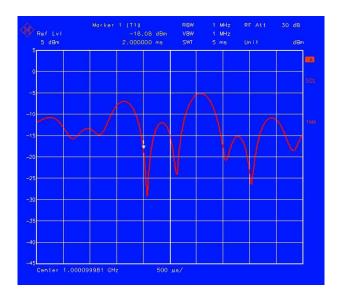

Second Noise Generator ABFS-B3 represents an additional noise source for a further output. This second noise generator is either assigned to the second channel of the basic ABFS (with first noise generator ABFS-B1 for the first channel) or to the first channel of the second fading simulator ABFS-B2.

Fading profiles of the Rayleigh, Rician, Pure Doppler, Lognormal or Suzuki method can be assigned to each of the propagation paths irrespective of the selected circuit (see Fig. 3).

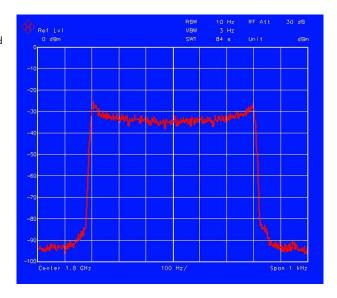

In addition to the fading profiles mentioned, the following parameters can be defined for each propagation path:

- Path attenuation
- Delay time
- Doppler frequency or speed between transmitter and receiver
- Coupling to another channel

Many fading models (eg GSM Rural Urban, Typical Urban) have already been programmed in ABFS. The user can quickly recall these default settings and also modify the parameters. Typical Rayleigh fading profile

Rayleigh fading (Doppler spectrum), generated at a speed of 180 km/h (RF = 1.8 GHz)

Why fading tests:

Short-time signal fading, as caused by multipath propagation, strongly affects the error rate of the received signal due to the short symbol periods in digital mobile radio

Modern digital systems overcome these problems with the aid of appropriate error control coding methods as well as algorithms for delay equalizing. Interleaving is employed to overcome the problem of losing large parts of the messages.

Resistance to fading is an essential quality criterion of digital mobile radio systems and means a considerable competitive advantage for the manufacturer.

Tests with real-world signals using fading simulators are a must to spot the weak points in new concepts at an early stage so that appropriate modifications can be made.
